Healing the Healers: Legal Remedies for Physician Burnout

Sharona Hoffman

ABSTRACT

A career as a doctor was long considered to be among the best professional paths that one could pursue. But medicine may no longer be the sought-after career that it once was. All too often, doctors, struggling with the demands of electronic health record systems and a myriad of administrative and regulatory responsibilities, find that they fail to derive much joy from their work and become victims of burnout. Physician burnout is an acute concern in the medical community, with forty-four percent of doctors reporting that they suffer from it. Physician burnout is a public health threat. Doctors who are profoundly distressed cannot provide their patients with the highest quality of care.

Thus far, physician burnout has received little if any notice in the legal literature. This Article argues that the problem deserves and requires legal attention. First, health care regulations relating to health information technology, insurance, and many other matters are partly responsible for physician burnout and must be streamlined. As a prime example, electronic health record systems are now heavily regulated, but rather than improving the quality and usability of products, the regulations needlessly overburden clinicians. Second, the government traditionally oversees and protects the health and well-being of the American workforce. This is especially true for safety-critical jobs, such as those in the transportation industry. Likewise, physicians should be understood to be doing safety-critical work because patients put their lives in clinicians’ hands. This Article, therefore, aims to fill a void in the literature by analyzing physician burnout through a legal lens and by developing recommendations for legal interventions to address the problem.

HEALING THE HEALERS: LEGAL REMEDIES FOR PHYSICIAN BURNOUT

INTRODUCTION

In a 2018 article in The New York Times Magazine, Dr. Abraham Verghese wrote of a “disease” from which an increasing number of his colleagues are suffering. He describes a young colleague who is experiencing “existential despair” at a time that should be “the honeymoon of a career.” The “disease” is commonly known as physician burnout.

Dr. Verghese explains the problem as follows:

My young colleague slumping in the chair in my office survived the student years, then three years of internship and residency and is now a full-time practitioner and teacher. The despair I hear comes from being the highest-paid clerical worker in the hospital: For every one hour we spend cumulatively with patients, studies have shown, we spend nearly two hours on our primitive Electronic Health Records, or “E.H.R.s,” and another hour or two during sacred personal time. But we are to blame. We let this happen to our trainees, to ourselves.

A career as a doctor has been long considered to be among the best professional paths that one could pursue. Many parents have fervently hoped that one day they would be able to say “my son/daughter the doctor,” and many students have dedicated themselves tirelessly to their studies so that they could enter medical school and ultimately enjoy the many rewards of being a physician.

But medicine may no longer be the appealing career that it once was. All too often, in light of financial, technological, regulatory, and other pressures, doctors find that they fail to derive much joy from their work and become victims of burnout. Physician burnout has become an acute concern in the medical

community. It has been called an epidemic, pandemic, and public health crisis.

Thus far, however, it has received little if any attention in the legal literature. This gap is surprising because health care regulations relating to EHRs, insurance, and many other matters are partly responsible for physician burnout. Physicians consistently report being overwhelmed by the demands of the labyrinth of American health care laws and regulations with which they must comply. As a prime example, electronic health record (EHR) systems are now heavily regulated, but rather than improving the quality and usability of products, the regulations needlessly overburden clinicians. This Article, therefore, aims to begin to fill this void and to analyze physician burnout through a legal lens.

Burnout is a syndrome that is characterized by emotional exhaustion, depersonalization, and dissatisfaction with one’s work accomplishments. According to a recent study, in 2017, forty-four percent of U.S. doctors identified as suffering from at least one symptom of burnout, while the burnout rate was only twenty-eight percent in the general working population.

A profoundly unhappy health care workforce is unlikely to provide the highest quality of care and at times may provide poor care that endangers patient welfare. It can also exacerbate the already worrisome problem of health care provider

11. See infra note 147 and accompanying text for definition of usability.
shortages.\textsuperscript{15} Many doctors have reduced their hours in order to alleviate work pressures, retired early, or abandoned clinical practice for jobs in medical education, administration, or industry.\textsuperscript{16} Medical students, perceiving clinicians’ distress, may avoid fields with high burnout rates, such as general internal and emergency medicine, or may choose not to be clinical caregivers altogether.\textsuperscript{17} Burnout, therefore is a public health threat that policy-makers cannot ignore.

A variety of medical organizations have undertaken initiatives to study and formulate recommendations to alleviate physician burnout.\textsuperscript{18} One might assume that the task of solving the burnout problem should be left to the health care industry.

In truth, however, the welfare of physicians and their patients is very much a legal concern as well. Policy-makers have enacted extensive regulations to govern safety-critical jobs such as positions of responsibility in the transportation industry, and these focus in part on the well-being of workers.\textsuperscript{19} For example, a federal regulation provides that “[n]o pilot of an airplane that has a crew of two pilots may be on duty for more than 16 hours during any 24 consecutive hours.”\textsuperscript{20}

Likewise, doctors perform safety-critical work when they treat their patients. Doctors routinely make life and death decisions about their patients. It is often within their power to cure sick individuals but also to injure them or end their lives through medical errors. Consequently, it is both sensible and necessary for the law to be employed to minimize burnout and enhance physician well-being.

Unfortunately, there is no single legal intervention that can solve the physician burnout problem. The article suggests a variety of changes that will constitute

\textsuperscript{17} Linzer et al., supra note 16, at 1584. See also infra notes 43, 85–86 and accompanying text.

\textsuperscript{19} See, e.g., 14 C.F.R. § 91.1062 (2018) (discussing duty periods and rest requirements for flight attendants). See also infra Part IV.

\textsuperscript{20} 14 C.F.R. § 121.505(b) (2018).
building blocks for addressing the physician burnout phenomenon.

The remainder of the Article proceeds as follows. Part I describes the physician burnout problem, including its nature, consequences, and causes. Part II analyzes the impact of electronic health record systems on physician burnout. It focuses on the shortcomings of the technology itself as well as on the burdens that various EHR-related regulations impose. The Article argues that rather than facilitating EHR system use and supporting physicians, the regulations worsen clinicians’ work conditions and exacerbate burnout. It also critiques the certification requirements for EHR products and highlights their failure to incorporate adequate usability testing. Part III discusses an additional but interrelated source of burnout: physicians’ frustration at having to rush through appointments and their inability to spend adequate time with patients. Their time is constrained both by crushing administrative burdens and by pressure to generate income. This Part also details self-help measures to which physicians have turned, namely, employing scribes to handle EHR data entry and establishing innovative direct primary care practices. Part IV develops the argument that the law is an appropriate and necessary tool for remedying the physician burnout problem. Part V proposes a series of legal interventions. These include streamlining regulatory requirements, expanding usability testing for purposes of EHR certification, enabling purchasers to conduct acceptance testing, assessing and reporting physician wellness indicators as quality measures, supporting providers’ own initiatives to ease burnout, and conducting further research to better understand the problem and identify effective solutions. Part VI concludes.

I. PHYSICIAN BURNOUT: THE NATURE OF THE PROBLEM

A. Physician Burnout

Burnout can be defined as “a syndrome characterized by emotional exhaustion and depersonalization (which includes negativity, cynicism, and the inability to express empathy or grief), a feeling of reduced personal accomplishment, loss of work fulfillment, and reduced effectiveness.”\(^{22}\)

Burnout in the health care professions is commonly measured using the Maslach Burnout Inventory (MBI).\(^{23}\) The MBI is designed to evaluate the frequency and intensity of burnout among members of the helping professions by

\(^{21}\) See infra notes 374-380 and accompanying text.\(^{22}\) Dzau et al., supra note 7, at 312.\(^{23}\) Shanafelt et al., supra note 13, at 3 (stating that the MBI is considered “the standard tool for measuring burnout”); Validated Instruments to Assess Work-Related Dimensions of Well-Being, NAT’L ACAD. MED. (2018), https://nam.edu/valid-reliable-survey-instruments-measure-burnout-well-work-related-dimensions/#purpose (asserting that “[t]he Maslach Burnout Inventory is the gold standard for research purposes.”).
HEALING THE HEALERS: LEGAL REMEDIES FOR PHYSICIAN BURNOUT

focusing on three phenomena: 1) emotional exhaustion, 2) a sense of diminished personal accomplishment, and 3) depersonalization.\textsuperscript{24} It contains twenty-two items, each of which is rated twice: once for frequency (on a seven-point scale ranging from never to every day) and once for intensity (using an eight-point scale ranging from none to major).\textsuperscript{25}

Several analysts have criticized the MBI and deemed it a flawed instrument.\textsuperscript{26} They assert that it suffers from a number of shortcomings, including that its cutoff scores are arbitrary and that it ignores factors such as childcare pressures, having a supportive partner, and financial worries.\textsuperscript{27} They also note that the MBI was developed initially to measure burnout among social service professionals and posit that it is unclear that it is an effective tool when assessing physicians.\textsuperscript{28}

Moreover, some experts question the distinction between burnout and depression and posit that in reality burnout is a depressive disorder.\textsuperscript{29} Arguably, the term “burnout” is preferred simply because it is less stigmatizing than “depression.” In response, defenders of the burnout concept assert that burnout is “job-related and situation-specific,” whereas clinical depressive conditions are “more general and context-free.”\textsuperscript{30} This controversy need not be resolved here. Whether it is called burnout or depression, it is clear that physicians are suffering work-related, adverse mental health consequences. Because the majority of the literature has embraced the term “burnout,” I will continue to use it in this Article.

I will use the term “depression” when discussing that condition specifically. By all accounts, a startling number of physicians report symptoms of burnout. Dr. Tait Shanafelt, who has studied physician burnout for many years, found that in 2017, forty-four percent of physicians in the United States suffered from one or more symptoms of professional burnout.31 He notes that burnout spiked in 2014, when it reached over fifty-four percent, and is now in the vicinity of its 2011 level.32 However, the percentage of physicians suffering from depression consistently increased from 38.2% in 2011 to 39.8% in 2014 to 41.7% in 2017.33 According to the study, during these years, the rate of burnout in the general working population in the United States remained steady at approximately twenty-eight percent.34 Other studies have confirmed the pervasiveness of physician burnout. In a 2015 survey, forty-six percent of physicians indicated that they suffered from burnout.35 The Medical Society of the State of New York (MSSNY) conducted a survey in 2016 and concluded that fifty-seven percent of New York physicians are burned-out.36 Moreover, only fifty-eight percent of New York physicians would choose to be doctors if they were currently selecting a career path.37 The 2016 Physicians Foundation survey concluded that among 17,236 respondents, forty-four percent had “somewhat or very negative” morale, forty-nine percent “often or always” felt burned-out, and forty-nine percent would counsel their children against pursuing a career in medicine.38 A 2018 study of U.S. resident physicians

31. Shanafelt et al., supra note 13, at 7.
32. Id. (stating that the 2011 burnout rate was 45.5%). It is noteworthy that the 2017 study was smaller than its predecessor, involving 4893 respondents compared to 6767 in 2014 and 7227 in 2011. Id. The 2017 study had a 17.1% response rate compared to the 2014 study’s 19.2% response rate. See Tait D. Shanafelt et al., Changes in Burnout and Satisfaction with Work-Life Balance in Physicians and the General US Working Population Between 2011 and 2014, 90 MAYO CLINIC PROC. 1600, 1600 (2015). Dr. Shanafelt explains that the positive change in burnout rates between 2014 and 2017 may be attributable to several factors. Physicians may have adjusted to using EHR systems, the unhappiest doctors may have left practice or reduced their hours to alleviate stress, and some employers have instituted effective wellness initiatives. Shanafelt et al., supra note 13, at 11.
33 Shanafelt et al., supra note 13, at 7.
35. Carol Peckham, Physician Burnout: It Just Keeps Getting Worse, MEDSCAPE 1 (Jan. 26, 2015), https://www.medscape.com/viewarticle/838437 (reporting that the self-reported burnout rate was just under forty percent in 2013 and increased to forty-six percent in 2015).
37. Id.
38. 2016 Survey of America’s Physicians: Practice Patterns and Perspectives, 2016 PHYSICIANS FOUND. BIANN. PHYSICIAN SURV. 1, 7 (2016), https://physiciansfoundation.org/wp-
concluded that even these freshly-minted doctors suffer from burnout at a rate of 48.8%, which is often accompanied by "career choice regret."^{39}

A recent large-scale international study may inform how we weigh the above conclusions. The systematic review examined 182 studies from forty-five countries that involved 109,628 physicians.^{40} It found "remarkable variability in published prevalence estimates of burnout, with estimates of overall burnout ranging from 0% to 80.5%.^{41} It attributed this broad range to significant differences in the ways burnout was defined and measured in the studies.^{42} Consequently, the review could reach no definitive conclusion about burnout prevalence among physicians globally. This finding may raise questions about the burnout figures cited in U.S.-focused studies as well.

The degree of physician burnout varies by specialty and demographics. Those in high-stress fields such as emergency medicine, general internal medicine, general surgery, and neurology, are at higher risk of burnout than those in dermatology, pathology, anesthesiology, or occupational medicine.^{43} In addition, female physicians and those under fifty-five years old are more vulnerable to burnout.^{44} To illustrate, according to the MSSNY study, sixty-three percent of female doctors in New York identified as experiencing burnout compared to fifty-three percent of male physicians.^{45} Furthermore, peak burnout in New York was evident ten to nineteen years after the completion of training.^{46} A different study involving 422 family physicians and general internists found that women physicians reported burnout nearly twice as often as did their male counterparts.^{47}

The burnout phenomenon has spread to other health care providers as well.

One study found that one-third of oncology physician assistants report burnout. A different study identified burnout as a serious problem among rural physician assistants. Studies of nurses have revealed alarming rates of burnout as well. One investigation concluded that burnout disproportionately affects nurses in neonatal intensive care units. Another found high burnout rates among nurses working in hospitals and nursing homes, reaching thirty-four and thirty-seven percent respectively.

The United States is not the only country exposed to physician burnout. By many accounts, it is prevalent internationally. For example, there are urgent calls to address physician burnout in Canada, the United Kingdom, Israel, and even Finland.

HEALING THE HEALERS: LEGAL REMEDIES FOR PHYSICIAN BURNOUT

Although the scope of the problem is global, this Article is limited to addressing professional burnout in the United States. While I do not wish to minimize the severity of the phenomenon among other health care professionals, I focus primarily on physicians in this piece.

B. The Consequences of Burnout

Burnout has far-reaching effects on physicians and patients. These fall generally into three categories: diminished physician well-being, poor quality of care, and workforce attrition.

1. Physician Well-Being

Burnout takes a heavy toll on physicians’ mental health. As noted above, it is characterized by emotional exhaustion, negativity, cynicism, and a sense of lack of accomplishment and job fulfillment.\(^{58}\) Not surprisingly, therefore, assuming that it is distinct from depression,\(^ {59}\) it can lead to depression.\(^ {60}\) In addition, physicians with high burnout scores suffer from insomnia and poor sleep quality at significantly higher rates than colleagues with lower levels of burnout.\(^ {61}\) Burnout victims are also vulnerable to marital problems, substance abuse, and even suicide.\(^ {62}\) Approximately four hundred physicians commit suicide each year in the United States.\(^ {63}\) Experts have noted that “[o]f all occupations and professions, the medical profession consistently hovers near the top of occupations with the highest risk of death by suicide.”\(^ {64}\)

An even larger number experience suicidal ideation, that is, thoughts of suicide with or without a plan to end one’s life.\(^ {65}\) In a study of 7905 surgeons, 501

or 6.4% reported suicidal ideation during the prior twelve months. Suicidal ideation was 1.5 to 3.0 times more common among surgeons who were forty-five and older than among their counterparts in the general population.  

2. Quality of Care

There is substantial agreement that physician burnout adversely affects care quality and patient safety. In a variety of studies, physicians self-reported that burnout caused them to make treatment mistakes. One national study of surgeons involved 7905 participants. Seven hundred of them (8.9%) reported that they had made what they consider to be a major medical error in the last three months. The researchers noted that “each one point increase in depersonalization, emotional exhaustion, and mental QOL [quality of life] score was associated with a 5% to 11% higher likelihood of reporting a recent major medical error.” Medical residents who identify as suffering from burnout similarly perceive that they provide a lower quality of care to patients. A study of emergency physicians, who work in one of the most stressful environments, also assessed themselves as providing “suboptimal care” when suffering from burnout. Researchers acknowledge, however, the possibility that the causal relationship is reversed and that making medical mistakes is what causes physicians to feel burned-out rather

than vice versa.74

Several studies have attempted to develop objective evidence of a link between burnout and adverse health care outcomes. For example, one investigation focused on 178 pairs of patients who had been hospitalized in the prior year and their physicians.75 It concluded that the depersonalization aspect of physician burnout was associated with lower patient satisfaction and longer recovery time after hospital discharge.76 A meta-analysis of eighty-two studies including 210,669 health care providers found “small to medium-sized relationships between burnout and both decreased quality of care and decreased [patient] safety.”77

A few studies have found that errors are associated with depression but not with burnout that has not progressed to depression. One study focused on 123 residents in three U.S. children’s hospitals, twenty-four of whom met the criteria for depression and ninety-two of whom met the criteria for burnout.78 It found that residents with depression made 6.2 times as many drug errors per resident month as those without depression.79 However, burnout alone did not appear to be associated with a higher rate of medication errors.80 Likewise, a study of thirty-one intensive care units in France found that medical errors were associated with clinicians’ depression but not burnout.81

3. Workforce Attrition

Physician burnout endangers patients not only through possible medical errors but also by contributing to already significant deficits in the physician workforce. By some accounts, physician shortages may reach crisis proportions in the near future.82 According to the Association of American Medical Colleges, by 2030,

74 Shanafelt et al., supra note 68, at 997 (conceding that the authors were “unable to determine whether distress causes errors or errors cause distress”).

82 See Aaron E. Carroll, A Doctor Shortage? Let’s Take a Closer Look, N.Y. TIMES, Nov. 7,
the United States will experience a shortage of between 42,600 and 121,300 doctors.\textsuperscript{83} In the area of primary care, it predicts a shortfall of between 14,800 and 49,300 by 2030.\textsuperscript{84}  

It is already difficult to recruit medical students to the fields of internal medicine and primary care because students perceive these to be high-stress jobs.\textsuperscript{85} Students observe physicians who are burned-out and opt for other specialties.\textsuperscript{86}  

This trend is extremely troubling because competent primary care is often vital to maintaining good health.\textsuperscript{87} Primary care physicians practice general medicine and are able to diagnose and treat a multitude of conditions as well as prevent illnesses through vaccinations, screening, consistent monitoring, and other preventive interventions.\textsuperscript{88} Ideally, primary care physicians maintain thorough familiarity with their patients’ health conditions and oversee all of their care.\textsuperscript{89} While specialists treat particular conditions in isolation, primary care physicians can ensure that a patient’s care does not become fragmented and is well-coordinated.\textsuperscript{90}  

Furthermore, because of the growing pressures of medical practice, some physicians are reducing their work hours or retiring early.\textsuperscript{91} For example, a study

\end{itemize}
HEALING THE HEALERS: LEGAL REMEDIES FOR PHYSICIAN BURNOUT

at the Mayo Clinic found that the percentage of its physicians working less than full-time increased from 13.5 to 16.0 between 2008 and 2014. These numbers correlated with burnout rates. Women in particular often choose to work part-time.

Many who have not already taken action to alleviate burnout assert that they plan to do so in the future. A 2008 study involving 7615 surgeons who were members of the American College of Surgeons found that approximately forty percent of participants experienced burnout and thirty-two percent reported “at least a moderate likelihood” that they would leave their current practice within the next two years. Among the latter, 58.5% indicated they planned to stop being surgeons and pursue other work. An analysis of data from the 2016 Physicians Foundation Survey revealed that only fifty-two percent of respondents planned to continue as they are in the next one to three years, and all others planned to take steps to improve their quality of life, such as reducing their hours, seeking a non-clinical health care job, or retiring.

As the American population ages, the demand for physicians will only grow. Professional burnout may be a significant hindrance to meeting this critical need.

C. The Causes of Burnout

What are the primary reasons for burnout among physicians in the United States? The literature identifies many causes.

In 2015, Medscape conducted a survey of physicians and inquired about burnout causes. Physicians were asked to rank the causes on a scale of one to seven. In order of importance, along with their average scores, they were as follows:

- Too many bureaucratic tasks (4.74)
- Too many hours at work (3.99)

YALE JOURNAL OF HEALTH POLICY, LAW, AND ETHICS 18:2 (2018)

- Insufficient income (3.71)
- Increasing computerization (3.68)
- The impact of the Affordable Care Act (3.65)
- Feeling like just a cog in a wheel (3.54)
- Too many difficult patients (3.37)
- Too many patient appointments in a day (3.34)
- Inability to provide patients with a high level of quality care (3.22)
- Lack of professional fulfillment (3.05)
- Difficult colleagues or staff (2.90)
- Inability to keep up with current research (2.85)
- Compassion fatigue (2.80)
- Difficult employer (2.80)

The MSSNY 2016 survey found the following drivers of burnout, listed in order of prevalence. The percentage of respondents who identified the stressor as a factor in burnout is indicated in parentheses.

- Length and degree of documentation requirements (65.99%)
- Extension of work into home life (e-mail, record completion, phone calls) (58.27%)
- Prior authorizations for medications/procedures/admissions (54.74%)
- Dealing with difficult patients (51.89%)
- EMR functionality problems (51.05%)
- CMS/State/Federal laws and regulations (44.33%)
- Lack of voice in being able to decide what good care is (40.39%)
- Hospital/Insurer imposed Quality Metrics (38.87%)
- Dealing with difficult colleagues (31.49%)
- Requirement for increased CME [Continuing Medical Education]/maintenance of certification (31.49%)

A 2014 survey conducted by the Wisconsin Medical Society listed three factors as the primary causes of dissatisfaction and burnout among physicians: decrease in direct patient care, EHRs, and poor work-life balance. Other experts emphasize that the cumbersome and time-consuming administrative tasks that contemporary physicians face are a root cause of burnout.

HEALING THE HEALERS: LEGAL REMEDIES FOR PHYSICIAN BURNOUT

Two interrelated sources of burnout emerge as repeated themes in the literature. First is the transition to EHRs and associated clerical burdens, and second is inadequate time for face-to-face interactions with patients. Each of these could potentially be addressed through regulation, and thus, the remainder of this Article will focus on these two drivers of physician burnout.

II. ELECTRONIC HEALTH RECORD SYSTEMS AND PHYSICIAN BURNOUT

The EHR system has become the “virtual patient” that many believe demands more time than human patients. This Part explains what EHR systems are and describes their benefits and shortcomings. It also analyzes the link between EHR systems and physician burnout. Finally, it describes and critiques the web of EHR-related regulations that are arguably key contributors to burnout. These include the Meaningful Use regulations, the Medicare Access and CHIP Reauthorization Act (MACRA) of 2015, and EHR certification requirements.

A. Electronic Health Record Systems

In 2004, President George W. Bush identified the transition from traditional paper records to EHRs as a priority for the federal government. President Bush set a goal of having all Americans’ health records computerized within ten years and established the Office of the National Coordinator for Health Information Technology (ONC) within the U.S. Department of Health and Human Services to promote and oversee this process. The transition accelerated under the Obama administration. The Health Information Technology for Economic and Clinical Health (HITECH) Act, part of the Obama stimulus plan, provided financial incentives for meaningful use of certified EHRs. Today the vast majority of

EHRs appear to have increased clerical burden for physicians and can distract some physicians from meaningful interactions with patients.”); Squiers et al., supra note 43, at 1120 (stating that the authors “believe that one important mismatch is obvious to most practicing physicians—the increasing demands of medical bureaucracy that is at odds with and distracts from their primary passions of medical practice (e.g. patient care, research, and teaching)

109. Id.
practices have adopted EHR systems. As of 2016, over ninety-five percent of hospitals eligible to participate in the HITECH incentive program and over sixty percent of all office-based physicians are using EHR systems in compliance with the program. Many more physicians have EHRs but have not fulfilled all of the incentive program’s requirements.

The Institute of Medicine, the Robert Wood Johnson Foundation, and other experts identified eight “core EHR functionalities” that could make them more useful and versatile than paper records:

Clinical documentation and health information display: EHR systems record and display a wealth of information such as diagnostic test results, allergies, medication lists, diagnoses, demographics, clinicians’ notes, advance directives, and more.

Results management: EHRs enable clinicians to search the record for details such as a patient’s laboratory test results and prior treatments, thus enhancing their access to needed information.

Computerized provider order entry and management (CPOE): Health care providers can order prescriptions, diagnostic tests, treatments, and referrals to other physicians electronically.

Clinical decision support: This is a potentially life-saving feature that generates alerts and reminders for clinicians. Examples are warnings about drug interactions or side effects, guidance regarding appropriate medication dosage, and prompts relating to preventive and wellness care.

MED. & ETHICS (SUPP. ISSUE 1), 77, 77 (2011).
113. See supra note 112.
HEALING THE HEALERS: LEGAL REMEDIES FOR PHYSICIAN BURNOUT

Electronic communication and connectivity: EHR systems enable medical team members to communicate online with each other, with other providers whom they might consult, and with patients. More communication can enhance the patient's treatment experience and results.

Patient support: EHR systems can facilitate patient education and access to health records. Some systems offer patients a personal health record, which is "[a]n electronic application through which individuals can access, manage and share their health information... in a private, secure, and confidential environment."116 The systems also may remind patients to pursue preventive and follow-up care.

Administrative processes: Additional components include electronic scheduling systems, insurance eligibility verification, billing, and claims processing. Clinicians can further use computerized tools to identify individuals who are potential candidates for clinical trials, who are taking drugs subject to recalls, or who are eligible for chronic disease management programs. EHR systems can also facilitate quality assessment, quality improvement, public health, and other initiatives.

Reporting and population health management: Health care providers can collect clinical data to meet government, private, and institutional reporting requirements.117

EHR systems advocates have touted the many benefits that they can yield. These include enhancing the quality of care, improving patient safety, saving costs, and facilitating medical research and public health initiatives.118 A key advantage is that EHRs eliminate the problem of illegible handwriting in physician notes and prescriptions.119

Nevertheless, many physicians complain bitterly that contemporary EHR systems and the regulations that govern them generate cumbersome and time-

118. SHARONA HOFFMAN, ELECTRONIC HEALTH RECORDS AND MEDICAL BIG DATA: LAW AND POLICY 15-23 (2016).
YALE JOURNAL OF HEALTH POLICY, LAW, AND ETHICS 18:2 (2018)

consuming work. Consequently, many believe that EHR systems are a significant cause of burnout.120

B. The Link between EHR Systems and Burnout

Contemporary physicians spend as much as fifty percent of their total work time on documentation.121 According to one study, for each hour that doctors spend face-to-face with patients, they spend up to two hours on documentation.122 Moreover, physicians spend one to two hours outside the office each day on computer work.123 This phenomenon has spawned a new term popular among health care providers: “pajama time.”124 A leading expert, Dr. Robert Wachter, has explained that “EHRs contribute to burnout by turning physicians into unhappy data-entry clerks.”125

A study of EHR system use at a community hospital concluded that even in the emergency room, physicians spent forty-four percent of their time on EHR work, which far exceeded the amount of time they devoted to direct patient care (twenty-eight percent).126 The EHR work required an average of four hundred mouse clicks per hour and thus 4000 clicks in a ten-hour shift.127

Of course, before the advent of EHR systems, physicians were also required

127. Id.
HEALING THE HEALERS: LEGAL REMEDIES FOR PHYSICIAN BURNOUT

to document their diagnoses and treatments thoroughly and to comply with health care regulatory requirements.\textsuperscript{128} However, by many accounts, computerization has exacerbated rather than alleviated the onus of these tasks.\textsuperscript{129}

The explanation for this perplexing change lies in the design and functionality of contemporary EHR systems. EHR products often have user interfaces\textsuperscript{130} that are not intuitive and are difficult to navigate.\textsuperscript{131} Fixed templates restrict physicians’ ability to enter information in sensible and natural ways, and patient charts are plagued by information overload.\textsuperscript{132} In the era of paper records, physicians could dictate notes or jot down notes at their own discretion, but now they spend up to six times longer on computer tasks.\textsuperscript{133}

Another inefficiency arises from excessive alerts and reminders, also called clinical decision support.\textsuperscript{134} Electronic alerts and reminders can save lives, and they are a welcome addition to the health care toolkit. However, in practice, they

\textsuperscript{128} See Ommaya et al., \textit{supra} note 121 (discussing clinical documentation and coding requirements).

\textsuperscript{129} Tait D. Shanafelt et al., \textit{Relationship Between Clerical Burden and Characteristics of the Electronic Environment with Physician Burnout and Professional Satisfaction}, 91 \textit{MAYO CLINIC} Proc. 836, 846 (2016) (noting that in their current form, EHRs have “a variety of unintended negative consequences that reduce efficiency, increase clerical burden, and increase the risk of burnout for physicians”).

\textsuperscript{130} The user interface is the “application that allows users to enter data into a computer and that presents data to the user.” \textit{EDWARD H. SHORTLIFFE & JAMES J. CIMINO, BIOMEDICAL INFORMATICS: COMPUTER APPLICATIONS IN HEALTH CARE AND BIOMEDICINE} 997 (2006).

\textsuperscript{132} \textit{HOFFMAN, supra} note 118, at 29-32.

\textsuperscript{133} Paul Dechant, \textit{How Does the EHR Drive Burnout? Let’s Count the Ways}, KEVINMD.COM (August 13, 2017), \texttt{https://www.kevinmd.com/blog/2017/08/ehr-drive-burnout-lets-count-ways.html}; Sun Young Park et al., \textit{The Effects of EMR Deployment on Doctors’ Work Practices: A Qualitative Study in the Emergency Department of a Teaching Hospital}, 81 \textit{INT’L J. MED. INFORMATICS} 204, 204 (2012) (concluding that implementation of an EHR system increased “documentation time four to five fold”); Lise Poissant et al., \textit{The Impact of Electronic Health Records on Time Efficiency of Physicians and Nurses: A Systematic Review}, 12 \textit{J. AM. MED. INFORMATICS} ASS’N 505, 508 (2005) (finding that CPOE increased physicians’ work time between 98.1% and 328.6%).

\textsuperscript{134} Megan E. Gregory et al., \textit{Electronic Health Record Alert-Related Workload as a Predictor of Burnout in Primary Care Providers}, 8 \textit{APPLIED CLINICAL INFORMATICS} 686, 688, 693 (2017) (finding that primary care physicians’ subjective perception that they had inadequate time to manage EHR alerts contributed to burnout); Tina Shah et al., \textit{Impact of a National QI Programme on Reducing Electronic Health Record Notifications to Clinicians}, BMJ QUALITY & SAFETY 1, 1 (2018).
can exacerbate burnout. A study of the primary care physicians working for the Department of Veteran Affairs revealed that seventy percent felt they could not effectively manage the number of alerts they received. Moreover, thirty percent indicated that during the prior year, they had missed patient test results because of alert burden and consequently delayed patient care. Another research project concluded that primary care physicians received a mean of 56.4 alerts with new information per day and spent an average of forty-nine minutes per day processing these alerts. All too many alerts are boilerplate notifications that relate to trivial drug risks that are not of clinical significance or matters that do not apply to the patient in question. According to one study, it takes over 331 alerts to prevent one adverse drug event, and just ten percent of notifications account for seventy-eight percent of cost savings from preventable errors. While alerts are worthwhile if they avert even one critical medical mistake and expense reduction is always appreciated, physicians commonly complain of “alert fatigue” and long for improved clinical decision support that would issue only serious warnings that could meaningfully enhance care.

Yet another source of information overload is the EHR’s copy and paste feature. The ability to copy narrative from a prior visit and paste it into new visit notes is designed to save clinicians time. Ironically, however, this feature may waste a great deal of time because it can make the medical record repetitive and excessively voluminous. Because of such “note bloat,” reviewing a patient’s record prior to a visit or locating particular details within it can become a slow and arduous task. Moreover, if the copied information is not carefully edited and updated, the new visit notes could be erroneous and mislead or confuse physicians. For example, in one reported case, the EHR of a patient who suffered

136. Id.

144. Id. (stating that “clinical notes have become bloated and difficult to read,” which forces clinicians “to go through a process of foraging to uncover important elements” of the record).
145. Sue Bowman, Impact of Electronic Health Record Systems on Information Integrity:
surgical complications and was hospitalized for many weeks indicated each day that this was “post-op day No. 2” because the note was repeatedly copied but never edited.146

Many clinicians have also complained generally about EHR system usability. Usability is a term that refers to “the extent to which a product can be used by specified users to achieve specified goals with effectiveness, efficiency, and satisfaction in a specified context of use.”147 Contemporary EHR systems suffer from a number of inadequacies that make them difficult to operate. For example, physicians find that they are difficult to navigate, display information poorly, do not enable users to search easily for data, disrupt the natural workflow of health care operations, and do not enable clinicians to use language effectively to tell the patient’s story.148 Experimentation with different user interface configurations has confirmed that optimized configuration can reduce physicians’ task load, shorten the time it takes to complete tasks, and even lower error rates.149 A few suggestions concerning features that enhance EHR usability are offered in Part V.B below.

EHR systems contribute to physician burnout not only because of the technology itself, but also because of the regulations that govern them. EHR regulations are analyzed in the next section.

C. The Regulatory Burden: Meaningful Use, MACRA, and Certification

In 2009, in an effort to dramatically advance EHR systems’ adoption, Congress enacted the HITECH Act.150 The law established an incentive program by which qualified health care providers could receive incentive payments for becoming meaningful users of certified EHR systems.151 Health care providers could receive incentive payments from Medicare through 2016 and from Medicaid

148. Id. at 808-11; Hoffman, supra note 118, at 29-30 (discussing EHR systems’ inflexibility and lack of customization); Ommaya et al., supra note 121, at 4 ("The patient’s story is . . . lost in the fog of self-populated content that adds pages but little purpose to the notes.").

149. Adil Ahmed et al., The Effect of Two Different Electronic Health Record User Interfaces on Intensive Care Provider Task Load, Errors of Cognition, and Performance, 39 CRITICAL CARE MED. 1626, 1627, 1633 (2011) (reporting on the design of a novel user interface that displayed “a subset of high-value data”).

151. Blumenthal & Tavenner, supra note 111, at 501; Hoffman & Podgurski, supra note 111, at 77. Providers could receive up to $44,000 through Medicare or $63,750 through Medicaid, depending on eligibility.
The program is now named the Promoting Interoperability (PI) Program. In order to implement the HITECH Act, the Centers for Medicare and Medicaid Services (CMS) issued a series of regulations that establish the standards for meaningful use and EHR system certification. Meaningful Use standards have also been incorporated into a second law, MACRA. This section addresses the regulations that are relevant to physician burnout and analyzes their pitfalls.

1. The Meaningful Use Regulations and MACRA

The Meaningful Use regulations and MACRA require physicians to perform a variety of functions using their EHR systems. Both have been criticized by commentators as overly burdensome and needlessly causing physicians distress. Both are analyzed below.

a. The Meaningful Use Regulations

The Meaningful Use regulations aim to ensure that clinicians put EHR systems to good use and employ them to improve health outcomes. They were rolled out in three stages, with the intention of allowing health care providers to adjust their practices gradually in order to fully utilize EHR systems. Stage 3 Meaningful Use regulations became effective in 2017. They establish eight objectives for professionals and hospitals that are eligible for incentives:

1) Protect patient health information
2) Generate and transmit prescriptions electronically
3) Implement clinical decision support
4) Use computerized provider order entry
5) Provide patients with electronic access to health information
6) Coordinate care through patient engagement
7) Engage in health information exchange

152. HOFFMAN, supra note 118, at 39-40. Eligible professionals had to select participation in either the Medicare or Medicaid program, but eligible hospitals could participate in both simultaneously. 42 C.F.R. §§ 495.60(e), 495.310(c), 495.310(g) (2018).

156. HOFFMAN, supra note 118, at 42.

157. Id.
8) Report data to public health authorities or clinical data registries\textsuperscript{158}

Health care providers participating in the PI program must also submit clinical quality measure (CQM) data to the Centers for Medicare and Medicaid Services.\textsuperscript{159} CQMs focus on six primary domains:

- Patient and Family Engagement
- Patient Safety
- Care Coordination
- Population/Public Health
- Efficient Use of Healthcare Resources
- Clinical Process/Effectiveness\textsuperscript{160}

Examples of CQMs are the "[p]ercentage of women 50-74 years of age who had a mammogram to screen for breast cancer"\textsuperscript{161} and the "[p]ercentage of patients 65 years of age and older who have ever received a pneumococcal vaccine."\textsuperscript{162} In 2018, eligible professionals receiving Medicaid EHR incentive payments must report six out of fifty-three CQMs.\textsuperscript{163}

b. MACRA

Physicians seeking Medicare payments must learn to comply with a new law

\textsuperscript{160} Id.

\textsuperscript{161} \textit{Breast Cancer Screening, CTRS. FOR MEDICARE & MEDICAID SERVS.} (May 14, 2018), \url{https://ecqi.healthit.gov/ecqm/measure/cms125v7}.

\textsuperscript{162} \textit{Pneumococcal Vaccination Status for Older Adults, CTRS. FOR MEDICARE & MEDICAID SERVS.} (May 14, 2018), \url{https://ecqi.healthit.gov/ecqm/measure/cms127v7}.

\textsuperscript{163} \textit{Program for 2018 Reporting, CTRS. FOR MEDICARE & MEDICAID SERVS.} (March 26, 2018), \url{https://ecqi.healthit.gov/ecqms/ecqm-news/cms-clarifies-ecqm-requirements-eligible-professionals-eps-under-medicaid-electronic}.
as well, MACRA, which went into effect in 2017.\textsuperscript{164} MACRA, in relevant part, aims to decrease clinicians’ administrative burdens by consolidating three quality reporting programs for Medicare purposes: 1) the Physician Quality Reporting System, 2) the Value-based Payment Modifier, and 3) Meaningful Use. It also adds a new performance category, however, called improvement activities.\textsuperscript{165} MACRA does not apply to hospitals and does not affect the Medicaid Promoting Interoperability program.\textsuperscript{166}

Under MACRA, physicians who wish to be paid by Medicare must participate in either the Merit-Based Incentive Payment System (MIPS) or an Advanced Alternative Payment Model (AAPM).\textsuperscript{167} MIPS creates a scoring system with a range from zero to one hundred and adjusts payment based on performance in four categories: quality, cost of care, promoting interoperability, and improvement activities.\textsuperscript{168} Based on their scores, physicians will receive positive, negative, or no Medicare payment adjustments.\textsuperscript{169} Thus, clinicians must scrupulously track and report the required data in compliance with complex and sometimes abstruse instructions in order to maximize Medicare payments and avoid penalties.\textsuperscript{170}

While most health care providers are subject to MIPS, some participate in an

\textsuperscript{166}42 U.S.C. § 1395w-4(q) (Supp. 2016); 42 C.F.R. § 414.1310 (2018); HOFFMAN, supra note 118, at 46.

\textsuperscript{167}MACRA Basics Merit-based Incentive Payment System (MIPS), AM. ACAD. FAM. PHYSICIANS (Jan. 25, 2018), https://www.aafp.org/practice-management/payment/medicare-payment/mips.html. The regulations establish an exclusion for those meeting the “low volume threshold” of two hundred or fewer Medicare Part B beneficiaries or $90,000 or less in billing for Part B covered services. See 42 C.F.R. §§ 414.1305, 414.1310(b) (2018).

\textsuperscript{168}In 2018 the categories were weighted as follows: quality – 50%, cost – 10%, promoting interoperability – 25%, and improvement activities – 15%. 42 U.S.C. § 1395w-4(q)(2)(A), (5) (Supp. 2016); 42 C.F.R. § 414.1380(c) (2018); MACRA Basics Merit-based Incentive Payment System (MIPS), supra note 167. In 2018 there were 275 available quality measures, and participants had to submit six that were relevant to their practice. See Quality Payment Program, CTRS. FOR MEDICARE & MEDICAID SERVS. (2018), https://qpp.cms.gov/mips/explore-measures/quality-measures?py=2018#measures.

AAM171 and are exempt from MIPS.172 Nevertheless, AAPM participants must still measure cost and quality and use certified EHR technology.173

c. Critique

If the foregoing sections were difficult for readers to follow, the regulations are all the more overwhelming for physicians who must comply with them. Undoubtedly, it is prudent to regulate EHR systems and track quality of care, and doing so should in principle promote improved health outcomes.174 However, critics posit that the current reporting requirements are excessively arduous, repetitive, and inflexible and thus exacerbate burnout.175

John D. Halamka and Micky Tripathi, both renowned EHR experts, co-authored a commentary on the HITECH era in the New England Journal of Medicine in 2017.176 They lamented that “confusing layers of regulations” caused the loss of the “hearts and minds of clinicians.”177 To illustrate, they argued that “quality measurement added data collection requirements that had a substantial

171. The Centers for Medicare and Medicaid Services define an alternative payment model (APM) as “a payment approach, developed in partnership with the clinician community, that provides added incentives to clinicians to provide high-quality and cost-efficient care. APMs can apply to a specific clinical condition, a care episode, or a population.” Quality Payment Program 8, CTRS. FOR MEDICARE & MEDICAID SERVS. (Oct. 26, 2016), https://www.cms.gov/Medicare/Quality-Initiatives-Patient-Assessment-Instruments/Value-Based-Programs/MACRA-MIPS-and-APMs/MACRA-Quality-Payment-Program-webinar-slides-10-26-16.pdf.

177. Id. at 907.
negative effect on usability with little return.”178 Another author complained that the Meaningful Use regulations disrupt workflow because they require doctors to perform EHR tasks that non-physicians could otherwise handle.179 Likewise, the Medicare Payment Advisory Commission has asserted that MIPS is very complex and burdensome.180

In his well-regarded book, The Digital Doctor: Hope, Hype, and Harm at the Dawn of Medicine’s Computer Age,181 Professor Robert Wachter critiqued the Stage 2 Meaningful Use regulations that preceded Stage 3. He posited that many of the mandates “depended on a clinical ecosystem and health care culture that did not yet exist.”182 For example, they required that more than five percent of patients “view, download, and transmit” their electronic health information to third parties.183 Thus, physicians had to invest time in encouraging patients to engage in activities in which they may have no interest and from which they may not benefit.

In addition, the regulations required hospitals to transmit discharge summaries electronically to other facilities,184 but they did not mandate that these summaries be useful to recipients. Consequently, some hospitals were spending time arbitrarily sending discharge summaries to other facilities for no good reason other than to “check a box on . . . [their] Stage 2 scorecard.”185

As a third example, Dr. Wachter cited the requirement that doctors be prompted by their EHRs to provide educational materials to ten percent of their patients.186 Doctors who routinely gave their patients information sheets about

182. Id. at 209.
184. 42 C.F.R. § 495.20(l)(11) (2018). Stage 3 retains this requirement. See 42 C.F.R. § 495.22(e)(5) (2018). MIPS has a related requirement. See Quality Payment Program, supra note 183 (requiring that “[f]or at least one transition of care or referral received or . . . [encounter with a new patient], the MIPS eligible clinician receives or retrieves and incorporates into the patient’s record an electronic summary of care document”).
185. WACHTER, supra note 181, at 209.
186. 42 C.F.R. § 495.20(j)(12)(ii) (2018). Stage 3 retains this requirement. See 42 C.F.R. § 495.22(e)(6) (2018). MIPS has a similar requirement. See Quality Payment Program, supra note 183 (requiring that clinicians “use clinically relevant information from certified EHR technology to identify patient-specific educational resources and provide electronic access to those materials to at least one unique patient”).
their conditions were not deemed in compliance. They had to find a way to have their EHR system prompt them to do so. According to the author, the regulations were so problematic that some clinicians referred to them as "Meaningless Abuse."\footnote{187}

2. EHR Certification

EHR certification regulations are designed to establish oversight and quality control for EHR products.\footnote{188} Unfortunately, they fall short of ensuring optimal usability of EHR systems. Consequently, many clinicians feel that rather than diminishing their administrative burdens, computerization has caused these burdens to become even heavier.\footnote{189}

a. Regulatory Requirements

Health care providers that wish to participate in the incentive program must operate certified EHR systems.\footnote{190} ONC, a division of the U.S. Department of Health and Human Services, oversees the Health IT Certification Program.\footnote{191} Ideally, certification should ensure that a product is safe and user-friendly and that it facilitates clinicians' clerical tasks to the extent possible. However, that is not the primary focus of this certification process.\footnote{192}

The certification regulations focus on enabling EHR system users to fulfill the Meaningful Use objectives.\footnote{193} To illustrate, one certification criterion is that the EHR system enable users to "electronically record, change, and access" medication, laboratory, and radiology or imaging orders.\footnote{194}

Another regulatory provision requires that "[u]ser-centered design processes must be applied to each capability an EHR technology includes."\footnote{195} User-centered design (UCD) prioritizes the cognitive and information needs of users.\footnote{196} Although UCD evaluates the design and development process and focuses on the product's

\footnote{193. 45 C.F.R. § 170.315 (2018).}

\footnote{194. 45 C.F.R. § 170.315(a)(1) (2018).}

\footnote{195. 45 C.F.R. § 170.315(g)(3) (2018).}

\footnote{196. Raj M. Ratwani et al., Electronic Health Record Vendor Adherence to Usability Certification Requirements and Testing Standards, 314 JAMA 1070, 1070 (2015).}
anticipated users, it does not specify precise methods for the design process and does not evaluate the product itself.

Vendors who wish to obtain certification must attest to implementing a UCD process and must conduct and report the results of usability testing on eight specified EHR functions. Vendors can develop their own UCD process or adopt well-respected processes, such as those published by the International Organization for Standardization or the National Institute of Standards and Technology.

In order to conduct usability testing, vendors recruit participants to engage in representative tasks relating to the eight EHR capabilities. Vendors then measure the amount of time it takes to complete the task, the number and types of errors found, and subjective user satisfaction with the way the EHR system operated. According to ONC, vendors should include at least fifteen participants, and reports are made public once the EHR product is certified.

b. Usability Testing Critique

The certification process focuses only on a narrow set of technical meaningful use requirements in a controlled laboratory setting, and vendors are given testing scenarios in advance. Thus, testing does not examine the product’s capabilities in wide-ranging and diverse circumstances, such as those that exist in the real world.

Moreover, vendors maintain a great deal of discretion with respect to usability

199. Ratwani et al., supra note 196, at 1070.
201. Schumacher & Lowry, supra note 200, at 18-19.
204. Id.
and invest varying amounts of resources in it.\textsuperscript{205} According to one study, the quality of vendors’ UCD processes ranges from well-developed to basic to misconceived.\textsuperscript{206} A second study led by the same investigator found “a lack of adherence to ONC certification requirements and usability testing standards among several widely used EHR products that were certified as having met these requirements.”\textsuperscript{207}

The American Medical Association and MedStar Health’s National Center for Human Factors in Healthcare have criticized the usability process for its “narrow focus on only eight capabilities among the dozens required by the ONC for the Meaningful Use (MU) program and to the absence of best practices in the certification process.”\textsuperscript{208} They assert that many vendors do not implement best practices and are nevertheless certified by ONC.\textsuperscript{209}

Consequently, researchers cite persistent problems in the areas of data entry, alerts, interoperability of different systems, visual displays, availability of information, automation, default settings, workflow disruptions, electronic ordering, test results management, and more.\textsuperscript{210} EHR systems remain plagued by poor usability and excessive “click burden.”\textsuperscript{211} These deficiencies not only contribute to physician burnout, but also may lead to medical errors and endanger patients.\textsuperscript{212}

III. INABILITY TO SPEND ADEQUATE TIME WITH PATIENTS

One of the consequences of the very heavy administrative burdens with which physicians are saddled is that they spend relatively little time interacting face-to-face with patients. Thus, many lament that they cannot do what they love to do most as members of the healing profession.\textsuperscript{213} Physicians are forced to rush through examining patients, listening to them, thoughtfully considering the reasons

YALE JOURNAL OF HEALTH POLICY, LAW, AND ETHICS 18:2 (2018)

for their concerns, explaining diagnoses and treatments, and answering questions.214 These time pressures contribute to physicians’ dissatisfaction and burnout.215 This section analyzes the length of time allotted for patient visits, the causes of short patient visits, and two self-help measures that physicians are using to increase the time they have with patients.

A. Time Allotted for Patient Visits

The average primary care visit is fifteen to twenty minutes.216 While relatively simple medical problems can be addressed in a few minutes, many cannot.217 Experts note that because of our aging population, an increasing number of patients have multiple chronic ailments and complex needs.218 The time allotted, therefore, is frequently inadequate to the task. Some experts posit that effective primary care visits often require thirty minutes or more.219

Medscape conducted its 2018 Physician Compensation Report by electronically surveying 20,329 physicians in twenty-nine specialties.220 The survey included a question about the number of minutes doctors generally spent with patients during visits.221 They responded as follows:

- Five percent spent fewer than five minutes per visit;
- Twenty-two percent spent between nine and twelve minutes per visit;
- Twenty-nine percent spent between thirteen and sixteen minutes per visit;
- Thirty-three percent spent between seventeen and twenty-four minutes per visit;

221. Id. at 32.
HEALING THE HEALERS: LEGAL REMEDIES FOR PHYSICIAN BURNOUT

- Eleven percent spent twenty-five minutes or longer per visit.\(^{222}\)

The 2016 Physicians Foundation survey revealed that only fourteen percent of doctors felt they have the time necessary to provide the highest quality of care.\(^{223}\) Furthermore, eighty percent reported being overextended or at capacity and lacking time to see any additional patients.\(^{224}\)

Even highly specialized physicians who care for complex patients are rushed for time. A study of neurologists found that they suffered burnout partly because of reduced time with patients and consequently diminished enjoyment of their work.\(^{225}\)

It is important to recognize that patient visits that are too short have adverse consequences not only for physicians who are more likely to suffer burnout, but also for patients. Time pressures can lead to poor patient care.\(^{226}\) Providers may take abbreviated patient histories, conduct superficial physical exams, and order unnecessary tests because they do not have time to be more thoughtful about what course to pursue.\(^{227}\) Thus, spending more time with patients could not only increase physicians' career satisfaction but could also enhance patient welfare, improve treatment outcomes, and save the health care system money.\(^{228}\)

B. Reasons for Short Visit Times

Physicians face an accumulation of demands and responsibilities that take time away from patient appointments. This section will focus on two areas: administrative work and financial pressures.

1. Administrative Work

The work of operating EHR systems and complying with associated regulations, discussed extensively above, is no small factor in limiting the time that
doctors can devote to face-to-face patient care. However, it is not the only culprit.

Physicians grapple with a myriad of additional administrative demands arising from regulatory mandates and other obligations. For example, as noted above, MACRA includes numerous reporting requirements, many of which are unrelated to EHR systems. Physicians must also interact with public health authorities and submit certain data to them, such as information about communicable diseases.

Health care payers and regulators require clinicians to report a multitude of quality and performance measures. The National Quality Measures Clearinghouse lists over 2500 performance measures. CMS alone uses as many as 1700 measures with which providers may have to be familiar. Performance measures have faced increasing criticism in recent years. One survey found that only twenty-seven percent of physicians felt that contemporary measures were "moderately or very representative of the quality of care" they provide. Another assessed the validity of eighty-six of the 271 measures in MIPS's Quality Payment Program and determined that only thirty-two were valid, whereas thirty were invalid, and twenty-four were of uncertain validity.

Obtaining insurance payments from either private or public insurance payers is a work-intensive and time-consuming endeavor. In addition to reporting quality measures, health care providers must be prepared to handle eligibility verification, billing, prior authorization, appeals of coverage denials, referrals, and much more. Billing requires expertise with respect to Evaluation/Management Codes, International Classification of Diseases Tenth Revision (ICD-10), Relative Value Units, and the Geographic Practice Cost Index, among other matters.

Another source of administrative tasks is board certification, evaluation, and accreditation by professional entities such as the American Board of Internal Medicine,239 the Joint Commission,240 the National Committee for Quality Assurance,241 and others. Interacting with vendors and suppliers and ordering medical equipment likewise can entail considerable administrative hassles.242

2. Financial Pressures

Financial pressures abound as well. Medicare established the relative value unit (RVU) payment model in the early 1990s.243 RVUs are calculated based on the physician’s work, the expenses of the medical practice, and the cost of medical malpractice insurance.244 To illustrate, in 2014, an intermediate office visit was assigned 3.01 RVUs, a diagnostic colonoscopy 11.03 RVUs, and a total hip replacement 38.94 RVUs.245

In order to enhance their total RVUs, health systems began to pressure physicians to increase the number of patients they saw and meet daily visit targets.246 The reimbursement system incentivizes all clinicians “to do more in order to be paid more.”247 Even salaried physicians working for well-established medical centers face powerful financial inducements. The majority receive “productivity bonuses.”248 In some cases, their salaries are directly tied to RVUs, or they suffer wage deductions if their RVUs are too low.249

239. Certification by the American Board of Internal Medicine (ABIM), AM. BD. INTERNAL MED., https://www.abim.org/about/mission.aspx (“Certification by the American Board of Internal Medicine (ABIM) has stood for the highest standard in internal medicine and its 20 subspecialties.”).

ELISABETH ROSENTHAL, AN AMERICAN SICKNESS: HOW HEALTHCARE BECAME BIG BUSINESS AND HOW YOU CAN TAKE IT BACK 37 (2017); Dhruv Khullar et al., How 10 Leading Health Systems Pay Their Doctors, 3 HEALTHCARE 60, (2015) (finding that of ten leading health systems, five “use productivity-adjusted salaries”).
249. ROSENTHAL, supra note 248, at 37.
Medical employers routinely hire consultants and health care advisory firms in an effort to increase revenues.\(^{250}\) Today, few physicians work independently. Over seventy-five percent of doctors were employed by large health care organizations in 2014,\(^{251}\) and forty-two percent were employed by hospitals as of 2016.\(^{252}\) A majority of physicians thus work in environments that are likely influenced by fiscal consultants and the income-maximizing pressures they create.

3. **Loss of Clinical Autonomy**

A related concern is that physicians employed by large organizations often feel that they are deprived of clinical autonomy. The 2016 Physicians Foundation survey found that loss of autonomy was the second most commonly cited reason for job dissatisfaction, behind only regulatory and paperwork burdens (listed by 58.3% and 31.8% of respondents, respectively).\(^{253}\) Remarkably, a 2018 study concluded that physicians in practices with five or fewer doctors in New York City had only a 13.5% burnout rate.\(^{254}\) The researchers attributed the very low burnout rate to the independence that physicians in small practices enjoy.\(^{255}\) Among other benefits, such autonomy allows doctors to spend more time with patients and form deeper relationships with them.\(^{256}\)

Because of administrative and financial pressures, most contemporary physicians are said to “have one eye on the patient and one eye on the clock.”\(^{257}\) This phenomenon takes a toll both on patients and doctors who often feel profoundly disappointed with a career that they assumed would enable them to focus first and foremost on caring for their patients.

HEALING THE HEALERS: LEGAL REMEDIES FOR PHYSICIAN BURNOUT

C. Physicians’ Efforts to Increase Time with Patients

Some doctors have taken matters into their own hands. They have crafted partial solutions to alleviate some of the burdens contributing to physician burnout. This section will analyze two approaches: 1) scribes and 2) direct primary care.

1. Scribes

Scribes are professionals who shadow physicians and do the work of EHR data entry while the doctors interact with patients.258 Employing a scribe can significantly reduce the time the doctor must spend on documentation.259 Doctors employed close to 17,000 scribes in 2016,260 and the number is expected to grow to 100,000 by 2020.261 At least twenty-two companies supply scribes and provide them with pre-employment training.262 Scribes are often pre-medical college students or graduates.263

Not all physicians are equally enthusiastic about scribes.264 Some doctors and patients may be concerned about privacy because scribes learn sensitive information about patients and must be trusted to maintain confidentiality.265 In addition, incompetent or careless scribes could introduce errors into EHRs.266 Perhaps most importantly, scribes require salaries and thus could reduce the income of medical practices.267 According to Salary.com, medical scribe salaries

262. George A. Gellert et al., The Rise of the Medical Scribe Industry: Implications for the Advancement of Electronic Health Records, 313 JAMA 1315, 1315 (2015). See, e.g., Who We Are, SCRIBEAmericA (Aug. 2018), https://www.scribeamerica.com/who_we_are.html (stating that ScribeAmerica is “the nation’s most frequently used medical scribe company with more than 15,000 employees in 50 states providing professional services for over 2,000 clients”).

Robert Pranaat et al., Use of Simulation Based on an Electronic Health Record Environment to Evaluate the Structure and Accuracy of Notes Generated by Medical Scribes: Proof-of-Concept Study, 5 JMIR MED. INFORMATICS e30 (2017) (finding that “there was a wide inter- and intrascribe variation in accuracy for each section of the notes with ranges from 50% to 76%”).
267. Id.
YALE JOURNAL OF HEALTH POLICY, LAW, AND ETHICS  18:2  (2018)

ranged from $27,637 to $36,498 in 2018, with an average of $33,162.268

Scribe advocates have responses to all of these objections. Studies show that
patients are generally comfortable with scribes in the examination room.269
Moreover, when data is entered by time-strapped clinicians in often chaotic
circumstances, EHRs can easily become replete with errors.270 Scribes whose sole
or primary job is to enter data may actually increase EHR accuracy.271 Finally,
according to some experts, scribes enhance rather than diminish income for
medical practices. When physicians are freed of some of their documentation
duties, they have time to see more patients. The added income can compensate for
scribes’ modest wages or even exceed them.272 To illustrate, one study of a
cardiology clinic in Minnesota found that physicians who used scribes were ten
percent more productive than those without scribes.273 As a result, use of scribes
increased the clinic’s annual revenue by $1,372,694 at a cost of only $98,588.274
A second study concluded that two full- time scribes would increase the earnings
of a small office of seven family physicians by $168,600 per year at an annual cost
of only $79,500.275 Overall, many physicians have found that scribes significantly
improve their work quality and, consequently, job satisfaction.276 Note, however,
that if hiring scribes translates into pressure to schedule a larger number of patient
appointments and does not create opportunities to devote more time to each patient,

more satisfied with how their clinic went, the length of time they spent face-to-face with patients,
and the time they spent charting.”); Hafner, supra note 258.
burnout rates are unlikely to improve.

Some physicians delegate clerical tasks to others without using professional scribes.277 Various organizations have health coaches, medical assistants, or nurses that help with documentation and other tasks.278 Others have “flow managers” that guide physicians’ activities with the aim of improving efficiency and saving time.279 Many experts emphasize the importance of teamwork and its potential to improve physician well-being.280 In a team model, certain work can be delegated to non-physicians such as nurse practitioners so that doctors can spend more time with patients, doing the work they enjoy most and do best.281 However, expanding staff to include new team members can also complicate the work environment and require additional coordination, and thus may generate stress and even costs. This section has focused on scribes because their job in particular is to alleviate the burdens of EHR data entry.

2. Direct Primary Care and Concierge Medicine

A more radical approach to freeing up time for patient care is to devise new medical practice settings that remove some of the shackles that encumber contemporary physicians. Direct primary care (DPC) is a model that is being adopted by a growing number of clinicians.282 As of early 2018, there were at least 770 DPC offices operating in forty-eight states.283

DPC physicians provide all of their patients’ primary care for a monthly fee that commonly ranges between twenty-five and eighty-five dollars.284 Consequently, DPC has been described as a “subscription” or “retainer” form of

---

278. Id.
279. Id.
practice.285 A key advantage from the physicians’ perspective is that DPC practices generally do not bill insurers and rely instead on the income they receive directly from patients.286 Thus, DPC doctors are liberated from the considerable hassles of billing private insurers, Medicare, or Medicaid and are spared the expense of hiring staff to do this administrative work. Note, however, that DPC patients still need health insurance to cover non-primary care services, such as visits to specialists or treatment in hospitals.287

Because they have low overhead costs and a predictable income that is not dependent on the vicissitudes of insurance coverage, DPC physicians feel they can afford to treat fewer patients and spend much more time with them.288 DPC physicians generally accept six hundred to eight hundred patients rather than the typical patient panel of 2000 to 2500 that family physicians ordinarily have.289 Consequently, DPC doctors pride themselves on their availability and responsiveness to patients.290 As a result, they often derive greater career satisfaction than those in traditional practice settings.291

A well-known DPC practice is Atlas MD, located in Wichita, Kansas.292 On its website, Atlas MD states that each of its physicians attends to only five-hundred patients and that the practice offers “[s]ame-day scheduling with little to no waits and extended visits of an hour or more, if you’d like.”293 Among the benefits it furnishes are house calls, when needed, and round-the-clock accessibility to physicians.294 Atlas MD has a tiered fee schedule as follows:

- Adults 20-44 years old, $50/month;
- Adults 45-64 years old, $75/month;

286. Eskew supra note 282, at 12; Kyle Rowe et al., Direct Primary Care in 2015: A Survey with Selected Comparisons to 2005 Survey Data, 10 KAN. J. MED. 3, 6 (2017) (finding that between 2005 and 2015 the rate of insurance billing significantly diminished).

291. Id.

293. Id.

HEALING THE HEALERS: LEGAL REMEDIES FOR PHYSICIAN BURNOUT

- Adults 65+ years old, $100/month. 295

Atlas MD has also developed a “Direct Care Curriculum,” offering advice to physicians interested in establishing their own DPC practices. 296

An alternative to DPC is concierge medicine. Concierge practices are more common than DPC offices, numbering as high as 12,000 in 2014. 297 Like doctors with DPC practices, concierge physicians charge patients monthly fees and maintain a relatively small patient panel, which enhances their job satisfaction. 298 However, concierge practices generally continue to bill insurers for their services and thus must grapple with the regulatory and administrative burdens associated with that activity. 299 They also charge much higher monthly fees—according to one source $183 per month on average in 2015. 300 Consequently DPC has been called “concierge care for the masses.” 301

The DPC/concierge medicine model is not without critics. For the sake of clarity and brevity, I will address only DPC in the remainder of this section, but many of the arguments apply to the higher-end concierge practices as well.

One concern relates to DPC practices’ lack of participation in Medicare and Medicaid. Because they need not comply with Medicare and Medicaid regulations and their associated reporting requirements, these practices may be less accountable than other providers. 302

Because DPC physicians see fewer patients per day than others, some are concerned that a proliferation of these practices will reduce overall access to care and worsen physician shortages. 303 Potentially, the DPC phenomenon could exacerbate health disparities. This is because it might be unavailable to disadvantaged individuals who cannot pay monthly fees or do not live near a DPC

298. HOFFMAN, supra note 90, at 75.
303. Doherty, supra note 285, at 950 (noting concerns that DPC may impede access for patients who cannot afford the monthly fees); Weisbart, supra note 287, at 10.
office, and the trend could absorb many doctors who would otherwise see larger numbers of patients in traditional practices. DPC practices may also be tempted to turn away sicker patients who would require frequent appointments and complex care.

On the other hand, for those without insurance, paying modest monthly fees for comprehensive primary care may be an affordable and prudent approach. The alternative for uninsured patients is paying out-of-pocket for treatment, often after having neglected their health problems and facing a medical crisis that requires a costly visit to a hospital emergency room. Some practices have made particular efforts to be accessible to lower-income patients. For example, they may offer financially stressed patients discounted fees or even fee waivers.

In addition, advocates argue that concern that the DPC phenomenon will contribute to physician shortages is misplaced. The growing availability of urgent care centers and retail clinics means that patients can receive medical attention for certain conditions when they need it even if they cannot immediately see their primary care physician, and some prefer the convenience of such facilities. Thus, some patients may seek appointments with primary care physicians less frequently. In fact, the emergence of DPC practices could arguably diminish shortages if it keeps some doctors in practice when they would otherwise leave the profession.

According to the Direct Primary Care Coalition, twenty-five states have passed legislation addressing DPC. The laws generally define DPC as a medical

304. Doherty, supra note 285, at 950 (noting that DPC physicians have been found to have a disproportionately low number of Hispanic and African American patients and that this may be because the practices often choose to be located in wealthier communities).

HEALING THE HEALERS: LEGAL REMEDIES FOR PHYSICIAN BURNOUT

service that is not governed by state insurance regulations, and some establish certain patient protections. For example, the Oregon statute prohibits discrimination based on “race, religion, gender, sexual identity, sexual preference or health status” and requires DPC practices to make various disclosures to patients.

At the federal level, the Primary Care Enhancement Act was introduced in Congress in 2017. It would allow patients to use health savings accounts to pay DPC retainer fees, a practice that is currently illegal under Internal Revenue Service rules. If passed, such a law would make DPC practices more appealing to patients with such accounts and likely would promote DPC growth.

IV. WHY BURNOUT IS A LEGAL ISSUE

Physician burnout is a serious problem for the medical community. However, it is also a threat to the welfare of the public at large. Demoralized physicians who are prone to error or who reduce their hours or abandon the profession altogether will leave considerable medical needs unmet.

Physician wellness is an area that is ripe for legal intervention. The health and safety of workers, including health care providers, is traditionally a matter that is subject to government regulation. The Fair Labor Standards Act, the Occupational Safety and Health Act, a variety of anti-discrimination laws, and many other statutes protect American employees.

Safety-critical jobs are of particular concern to regulators. Federal regulations recognize that professionals who are responsible for public safety, such as transportation workers, must be well-rested when they are fulfilling job duties. Thus, regulations limit the work hours of air traffic controllers, pilots, flight

attendants, \textsuperscript{327} train employees, \textsuperscript{328} merchant marine officers, \textsuperscript{329} nuclear power reactor employees, \textsuperscript{330} and others. \textsuperscript{331} Likewise, the states have enacted legislation to ensure adequate rest for transportation workers, police officers, and firefighters, among others. \textsuperscript{332}

It is no stretch to posit that physicians are safety-critical workers as well. Missed diagnoses and careless treatments can surely injure or even kill patients. Thus, the mental health and well-being of doctors should be within reach of the law.

Regulators have already recognized the need to limit the fatigue and stress of some health care providers. For example, state regulations limit the nurse to patient ratios in hospitals and other health care facilities. \textsuperscript{333} Congress has also considered a federal bill entitled “The Nurse Staffing Standards for Hospital Patient Safety and Quality Care Act of 2017.” \textsuperscript{334} The bill would mandate specific minimum nurse-to-patient ratios, depending on the hospital unit, and would require hospitals to post notices regarding ratios and record actual ratios for each shift and unit. \textsuperscript{335}

To the relief of many young doctors, the Accreditation Council for Graduate Medical Education \textsuperscript{336} capped the number of hours that medical residents can work at eighty per week, with limited exceptions. \textsuperscript{337} Moreover, residents are restricted to twenty-four consecutive hours per shift, with an additional four hours allowed to manage care transitions. \textsuperscript{338} Yet, no law, regulation, or certification standard is

HEALING THE HEALERS: LEGAL REMEDIES FOR PHYSICIAN BURNOUT

designed to curb the demands placed on physicians who have completed their training and to ensure that their workload is manageable.

A second justification for legal intervention is that cumbersome regulations are partly responsible for physician burnout. As discussed extensively above, these regulations relate to EHR systems, insurance, quality measures, and other matters, and physicians complain bitterly about the regulations' impact on their workdays and job satisfaction. Consequently, it would be reasonable to focus on the maze of regulations that govern physicians to identify possible modifications that would alleviate physician burnout.

V. RECOMMENDATIONS

There is no sweeping reform that will constitute a panacea for physician burnout. At best, a number of modifications can be made that will incrementally yield improvement. This Part recommends the following changes: streamlining EHR-related regulations, expanding usability testing, measuring and reporting physician wellness, promoting mechanisms that are proven to ease burnout, and engaging in further study of the problem.

A. Streamlining EHR-related Regulations

As they modify and develop the regulatory landscape, health care regulators should concentrate on relieving physicians' workload pressures. Contemporary physicians must navigate a thicket of regulatory requirements and dedicate a vast amount of time to responding to the demands of Meaningful Use regulations, quality measures, MACRA, and more.

Legislators have not turned a blind eye to this problem. As noted above, MACRA consolidated three separate quality programs with the hope of diminishing clinicians' administrative workload, though some argue that it is doomed to fail in this regard.

Section 4001 of the 21st Century Cures Act requires the Department of Health and Human Services to develop a strategy and recommendations for reducing administrative burdens related to EHR use. ONC and CMS, which are units within the Department, have stated that they are committed to fulfilling this

341. Wilensky, supra note 233, at 2369. See also supra notes 164-166 and accompanying text.
mandate. To that end, they plan to revise evaluation and management (E&M) codes, which are used to document the nature and severity of patients' ailments for insurance billing purposes. The current E&M coding guidelines were created in 1995 and 1997, and many physicians consider them to be outdated and vexing.

ONC and CMS further hope to implement a "meaningful use overhaul," with three specific goals:

- Making the program more flexible and less burdensome;
- Emphasizing measures that require the exchange of health information between providers and patients;
- Incentivizing providers to make it easier for patients to obtain their medical records electronically.

The first objective, which is responsive to burnout concerns, is consistent with suggestions formulated by well-regarded experts. John Halamka and Micky Tripathy have suggested that the Meaningful Use regulations and MIPS be "dramatically simplified to focus on interoperability and a streamlined set of outcome-oriented quality measures." Interoperability refers to EHR systems' capacity to communicate with one another, exchange information, and operate seamlessly and in a coordinated fashion across organizations. While the architects of the EHR incentive program envisioned a fully interoperable National Health Information Network, current technology has fallen far short of enabling widespread interoperability.

Health economist Gail Wilensky has asserted that health care quality measures must be dramatically revised and simplified. Likewise, the American College of Physicians issued a position paper in which it made several recommendations for reducing clinicians' administrative tasks. It emphasized the need for all stakeholders, including public and private payers, professional societies, health

HEALING THE HEALERS: LEGAL REMEDIES FOR PHYSICIAN BURNOUT

care providers, patients, and EHR vendors to collaborate to determine how best to streamline administrative tasks.352

CMS has recently proposed removal of some quality measures, a step that is welcomed by many health care providers.353 As of this writing, the government has not detailed its plans or made final decisions about how it will simplify and trim its regulatory requirements.354

Developing a comprehensive blueprint for regulatory reform is beyond the scope of this Article. Instead, I offer a limited set of recommendations below. At the same time, it is essential that HHS remain steadfast in its commitment to the task of reducing administrative burdens and seek extensive input from all stakeholders.355 HHS must eliminate regulatory duplication and require only measures that will appreciably yield benefits to patients or public health. Doing so is vital for the well-being of the American health care workforce and therefore of the public at large.

B. Expanding Usability Testing in the EHR Certification Process and Requiring Acceptance Testing

Despite the general plea for streamlining articulated above, a few regulatory gaps must be filled in order to combat physician burnout. The first is in the area of certification and thus would target vendors rather than clinicians. EHR certification regulations should emphasize usability to a much greater extent.356 As noted above, current product testing prior to certification is minimal and is executed with varying degrees of thoroughness.357

Thus, pre-certification usability testing should be significantly expanded. To the extent possible, it is important to assess how EHR products perform in real-world settings. What difficulties do users encounter? How can EHR systems be made more efficient and user-friendly? The certification regulations should specify the methodology by which products will be evaluated, including the types of system failures and adverse events that clinician-testers will consider, how testers will detect, report, and confirm those failures, and what failure and adverse event

356. See supra Part II.C.2.

357. See supra Part II.C.2.b.

103
rates are acceptable (since rates of zero are not realistic).\textsuperscript{358}

To that end, certification should include much more extensive EHR system usability testing through simulated clinical workloads. Testing should employ real-world scenarios that vendors do not receive in advance.\textsuperscript{359} Such simulations do not require a product’s installation in a medical facility, but rather, they test various functions using fictional patient data.\textsuperscript{360} Authorized Certification Bodies\textsuperscript{361} should recruit clinician-testers and pay them, perhaps from a fund to which vendors seeking product approval contribute. Clinician-testers would be assigned to authorized testing laboratories\textsuperscript{362} and then to individual products’ testing processes.

Testing should be based on national usability standards developed by well-respected professional organizations such as the National Institute for Standards and Technology.\textsuperscript{363} Usability should be measured using appropriate usability metrics.\textsuperscript{364} Usability metrics measure user experience in an observable, quantifiable way, assessing a product’s effectiveness or efficiency, or the user’s satisfaction with respect to particular tasks.\textsuperscript{365}

Experts have noted that a variety of features can improve EHR system usability. As John Glaser, Senior Vice President, Population Health of Cerner Corporation, explains:

Context-aware software can whittle down choices to a manageable number so that users don’t have to scroll through dozens of options every time they need to enter an order. Advanced data visualization can help users focus on the most important information and correctly interpret that information.

Natural language processing is already making amazing progress at interpreting free text and pulling out individual data elements. It can potentially liberate clinicians from clicks and pull-down menus entirely. Combined with advanced voice recognition, it could even save them from typing.\textsuperscript{366}

HEALING THE HEALERS: LEGAL REMEDIES FOR PHYSICIAN BURNOUT

Other features that have been found to improve usability include color-coding abnormal test results and physician alerts in the EHR to reduce inappropriate test ordering.\(^\text{367}\) Certification must ensure that vendors are incorporating updated, proven technology to reduce physicians' clerical burdens.\(^\text{368}\)

However, simulated EHR usage is by nature based on specific assumptions about users and their environments. A limited number of simulations cannot take into account the very diverse population of EHR system users that have very different levels of computer skills and capabilities.\(^\text{369}\) Thus, they cannot anticipate all of the difficulties, obstacles, and mistakes that could arise in real health care facilities. As the American Medical Association and other experts observed, EHR systems “deployed in dynamic clinical settings do not always mirror the laboratory testing environment of the ONC Certification Program.”\(^\text{370}\)

Not all usability problems are attributable to flawed design or production. Some are caused by health care organizations' attempts to customize products to fit their own needs.\(^\text{371}\) Customization can be a serious contributor to usability problems, and health care organizations should be sure to employ highly skilled information technology specialists to prevent glitches and resolve them when they arise. But many problems are inherent to products as they are originally configured.\(^\text{372}\)

In an ideal world, effective usability testing would include clinical safety testing of EHR systems in their natural environments.\(^\text{373}\) Facilities would be asked to volunteer to be testing sites and have staff members use new EHR products over time in order to identify usability defects. Facilities could choose this undertaking if they are interested in the product and then would be rewarded with discounts if the EHR system is approved and they decide to purchase it. In addition, they could adopt the EHR system only to a limited extent and have just some clinicians use it in order to minimize disruption to the practice.

Admittedly, however, such clinical testing would pose significant challenges. First, it would require greater government oversight and more testing personnel.

\[^{367}\] Guo et al., supra note 8, at 140-41.
\[^{368}\] Kellogg et al., supra note 212, at 197 (stating that user-centered design must put “the cognitive needs of the clinician at the forefront of development, with a better understanding of the cognitive support that clinicians will need”).
\[^{369}\] HOFFMAN, supra note 118, at 51.
\[^{372}\] HOFFMAN, supra note 118, at 23-35 (discussing EHR system shortcomings).
\[^{373}\] See id. at 50-52 (recommended clinical safety testing).
Second, it would place demands on health care providers. For testing purposes, some would have to implement EHR systems that are not yet certified and that they may find to be a poor fit. Usability assessments, therefore, could exacerbate burnout at testing facilities in the short-term. Third, any incentive, such as price discounts, could create conflicts of interest. Facilities that find a new EHR system to be satisfactory may be motivated to report data that are excessively positive in order to ensure product certification and obtain discounts. Consequently, it is unrealistic to expect that the proposed clinical usability testing would be mandated in the near future.

In the alternative, CMS regulations should require that vendors allow customers to engage in acceptance testing. Acceptance testing is common in the software arena and is the final phase of testing, performed after a product is delivered and installed. It is designed to verify that users can accomplish their work using the system and that all of the customer’s requirements have been met. It often reveals flaws that were not apparent from simulated test data. Vendor contracts specify the terms of acceptance testing. If the customer does not accept the product pursuant to the contract terms, it may provide the vendor additional time to remedy defects or may reject the product and obtain specified remedies such as refunds of any money already paid. Contracts thus should provide that final payment is not due until the buyer has performed acceptance testing and accepted the product.

Acceptance testing would place little if any burden on health care providers. It is performed after a health care organization has selected an EHR system and signed a contract for its purchase. Without it, clinicians would simply have to adopt the system and begin using it despite any flaws. Acceptance testing will furnish an opportunity to demand that the vendor eliminate defects or to reject

376. SOMMERVILLE, supra note 374, at 80.

380. See supra note 356 and accompanying text.
severely problematic products before they are fully implemented and all members of the workforce undergo training to use them.

Finalizing EHR system implementation without thorough usability testing is akin to selling drugs that have not been responsibly tested in clinical trials involving actual patients. After investing substantial money, time, and effort in purchasing and implementing an EHR system, providers may be very reluctant to switch to a different product even if their existing system has significant flaws. Yet, EHR systems manage many aspects of patient care and have the potential to cause clinicians great misery. EHR systems also have serious safety implications for patients because documentation mistakes, inappropriate prompts, defective CPOE, and other aspects of the technology can lead to serious treatment errors. Consequently, it is critical that every certification process include comprehensive usability testing. In addition, it is important to allow buyers to conduct acceptance testing before finalizing their purchases. Ensuring that EHR systems rate highly in the usability area and facilitate rather than hinder clinicians’ administrative work could go far towards alleviating physician burnout.

C. Measuring and Reporting Physician Wellness

In addition to expanded usability testing, federal regulations should require the inclusion of physician wellness among the quality measures that are reported to CMS. Thus, MACRA and the Meaningful Use regulations should be revised to incorporate a physician wellness measure. Physicians should be required to complete the MBI or an equivalent assessment tool annually. This would not be an excessively burdensome task because it takes only ten to fifteen minutes to complete the MBI. Clinicians should then upload the results directly to a website.

382. The Challenges of Switching EHRs, MED. ECON. (Oct. 25, 2016), http://www.medicaleconomics.com/medical-economics-blog/challenges-switching-ehrs (stating that “while 60% of ambulatory EHR system users either dislike their system or are neutral about it, and nearly half say they wouldn’t recommend it to a colleague, only 15% of respondents say they’re considering switching to another system in the next year”). But see, Switching EHRs Becoming Norm in Healthcare, MED. ECON., (Oct. 25, 2017), http://www.medicaleconomics.com/med-ec-blog/switching-ehrs-becoming-norm-healthcare (stating that 62% of respondents indicated they had switched EHR systems during their career and that while half did so because of a change in employment, the other half did so because of dissatisfaction with the system they were using).
383. See supra Part II.B.
384. HOFFMAN, supra note 118, at 23-35 (discussing EHR system shortcomings); supra note 117 and accompanying text (discussing EHR system features).
385. See supra Part II.C.1.
386. See supra notes 23-25 and accompanying text.
387. Vibeke Hansen & Afaf Girgis, Can a Single Question Effectively Screen for Burnout in
provided by CMS. Direct submission will prevent health care employers from having an opportunity to manipulate outcomes in order to avoid negative financial consequences. Health care organizations should receive summary reports from CMS regarding burnout in their workforces. If CMS becomes concerned that clinicians are manipulating their MBI responses in order to protect their employers, it could require employers to submit annual data regarding the number of workers who left, switched to a part-time schedule, or retired early. Such data may serve as an additional indicator of the level of burnout in the workplace and be used to determine whether testing outcomes appear reliable.

CMS could then include physician burnout in its reimbursement calculus so that organizations with a burnout rate that exceeds a stated level would be subject to pay adjustments.\textsuperscript{388} CMS may need to adjust the allowable burnout rate for particular practice settings, such as high-stress specialties\textsuperscript{389} or resource-poor facilities in underserved areas. Small practices (to be defined by CMS) would be exempt from the reporting requirement because every physician would have an outsize influence on the overall burnout rate. Nonetheless, they should be encouraged to measure physician wellness and act to mitigate burnout.

Experts have noted that health care systems traditionally embrace the triple aim of enhancing patient experience, improving population health, and reducing costs, but they posit that a fourth aim should be added: cultivating providers’ wellness.\textsuperscript{390} Without workforce wellness, it is impossible to achieve the first three goals.\textsuperscript{391}

The adverse consequences of physician burnout are well-recognized.\textsuperscript{392} It can erode physicians’ mental health, reduce productivity, diminish the quality of care, and lead to workforce attrition.\textsuperscript{393} Burnout should be of concern to all health care providers because it can be associated with outcomes such as lower patient satisfaction, longer recovery time after hospital discharge, and even malpractice suits arising from medical errors.\textsuperscript{394}

Furthermore, promoting physician wellness is a professional ethical

obligation. The American Medical Association Code of Medical Ethics Opinion 9.3.1 establishes that "physicians have a responsibility to maintain their health and wellness" and "an obligation to ensure that colleagues are able to provide safe and effective care, which includes promoting health and wellness among physicians."

CMS pay adjustments would constitute a meaningful incentive for health care organizations to attend to clinician wellness. Concern for patient welfare and business interests should do so as well. Reporting and tracking of physician wellness is worthwhile because entities can implement a variety of interventions. Educational programs regarding mindfulness and stress management and small group discussions have proven useful. Likewise, support through teamwork or the hiring of scribes is helpful. Professional organizations have begun to develop additional tools to help health care providers combat burnout. Indeed, Dr. Tate Shanafelt credits such initiatives with helping to reduce burnout rates between 2014 and 2017. Collecting and storing burnout data from across the nation would also enable researchers to study the phenomenon in greater depth and better evaluate the efficacy of different interventions.

This Article proposes that CMS consider reported wellness measures in calculating reimbursement rates. However, these measures would be of even greater benefit to regulated health care entities themselves because they could use the information as a springboard for addressing the problem of burnout. Without

specific data about burnout in their own work environment, health care organizations may not be motivated to implement interventions.

D. Promoting Measures Proven to Ease Burnout

Health care regulations and laws should support and promote approaches that have proven successful in mitigating physician burnout. These include employing scribes and shifting to a direct primary care model.403

For example, Medicare could provide bonus points for MIPS scoring purposes to practices that hire scribes.404 Medicare already provides bonus points in a variety of circumstances. It awards a five-point bonus for small practices with fewer than fifteen clinicians and up to five bonus points for treating complex patients.405 Such a bonus would encourage providers to implement this self-help measure and may ultimately help pay for scribes’ wages. If other workplace interventions prove particularly successful, Medicare could provide bonus points for implementation of those as well.406

Congress should support direct primary care practices by passing the Primary Care Enhancement Act that would allow patients to use health savings accounts to pay DPC retainer fees.407 This benefit would help some patients cover the out-of-pocket costs of DPC and would thus provide important financial support for DPC practitioners. The law could include a sunset provision. Thus, if Congress determined that DPC was exacerbating physician shortages,408 it could choose not to renew the legislation at the end of the sunset period.

Policy-makers should use their considerable power to aid physicians in adopting mechanisms to combat burnout. If physicians feel empowered to promote their own wellness, they are much more likely to remain content and productive members of the clinical medicine profession.409

E. Addressing Patient Visit Length: A Need for Further Study

It is known that longer patient visit lengths improve physicians’ job satisfaction as well as treatment outcomes.410 It is therefore tempting to propose legal limits on

110
the number of patients physicians can see each day.

Other jurisdictions have considered or implemented such proposals. In 2015, the Alberta Medical Association suggested that general physicians see no more than six patients per hour (a number that seems alarmingly high). \(^{411}\) British Columbia doctors are subject to a fifty-patient daily cap, after which they get paid only half of their fee until they reach sixty-five patients, after which they are paid nothing (also very high limits). \(^{412}\) In June 2018, the British Medical Association passed a motion calling for a “sensible cap” on the workload of general practitioners. \(^{413}\)

American scholars have also suggested workload limitations. For example, one study of primary care physicians found that “visit rates above 3 to 4 per hour are associated with suboptimal visit content.” \(^{414}\) Similarly, experts have urged that it is irresponsible for primary care physicians to see more than twenty-five to thirty patients per day. \(^{415}\) For hospitalists, the suggested number has been lower, perhaps fifteen to eighteen per day. \(^{416}\)

Nevertheless, it would be inappropriate to formulate a legal mandate with absolute visit caps based on currently available evidence. The number of patients a physician can effectively treat in a day depends on a multitude of factors. These include the specialty, patients’ complexity, physician’s efficiency and work habits, the amount of work that is delegated to other team members, and more. \(^{417}\) We do

more time with patients can reduce hospitalizations and save the health care system money); supra Part III.A.

417. See Allen, supra note 416 (listing a large number of variables that should be considered in
not know what the workload tipping point is that causes physicians to suffer burnout. Nor have we verified the extent to which burnout or consequent depression causes medical errors. Many published studies have focused on physicians’ own perception of performing sub-optimally rather than on objective measure of poor outcomes.418 American physicians would likely find a cap objectionable because it would deprive them of discretion and could harm patients.419 A patient who is seriously ill may not be able to access her doctor if the clinician has already scheduled the allotted number of appointments for the day.420

Thus, researchers should continue to study burnout to determine its consequences and identify effective preventive mechanisms. Such causal inference studies are complex and must adjust for numerous variables that can impact physicians’ performance.421 If researchers develop a sound rationale for capping the number of patients seen per day (or per hour or week) in particular specialties, those caps could be established by law. Caps would need to take into account the nature of the patient visit and allow for exceptions in emergency situations. For example, one British proposal suggested that family doctors have twenty-five to thirty-five appointments per day if they were for routine care (e.g. sore throats or blood pressure checks) but see only fifteen patients per day if the individuals had complex problems.422

In the meantime, other proposed interventions, such as streamlining regulatory requirements, improving EHR usability, and encouraging the use of scribes,423 should diminish the demands of clerical work and leave physicians with opportunities to lengthen patient visits. Health care organizations must refrain from requiring that doctors fill freed-up time with extra appointments. Regulatory improvements must enable physicians to enjoy greater job satisfaction by spending more time with patients. They should not generate even more crowded appointment schedules and thus fuel the fires of physician burnout.

determining hospitalists’ patient loads).

VI. CONCLUSION

The American health care system suffers from numerous fractures and failures.\textsuperscript{424} Physician burnout is a core problem, which is as serious as any.\textsuperscript{425} Quality health care cannot be delivered without dedicated physicians who are happy with their work.\textsuperscript{426}

Health care professionals widely bemoan their existing professional circumstances. Physician and author Siddhartha Mukherjee critiques "the form-filling, diagnosis-coding, button-pushing culture of modern medicine."\textsuperscript{427} Dr. Thomas Schwenk writes in \textit{JAMA} that the "caring relationship has been lost for many physicians in the current system of fragmented, rushed, dysfunctional, digitized, corporatized, and costly medical care – a system that prizes efficiency over relationships, profits over common good, and volume over value."\textsuperscript{428} Philip Miller asks in \textit{Health Affairs}: "The question is, Will medicine remain a calling with patient care at its heart or become a mere occupation, characterized by bureaucracy and a focus on the bottom line?"\textsuperscript{429}

Physician well-being is a worthy cause that deserves the attention of both the medical community and policy-makers. Because public health is at stake, the law can no longer ignore the reality of physician burnout. Its power must be harnessed to launch a multi-faceted effort to combat the problem. Initiatives should include streamlining regulatory requirements, emphasizing usability in the process of EHR certification, measuring and reporting physician wellness indicators, supporting the use of scribes and direct primary care, and conducting further research to better understand burnout and identify additional solutions.\textsuperscript{430}

Policy-makers must work to restore the appeal of the medical profession and retain the physician workforce. The health of the nation is at stake.
