Essay

Speculative Undertakings: Rate Regulation as a Branch of Corporate Finance

James Ming Chen[†]

The law of regulated industries, particularly the obligation to secure “just and reasonable rates” for regulated services, is a highly specialized application of financial economics. Ratemaking, bluntly put, represents a regulatory exercise in capital asset pricing. As a matter of economics, this Essay describes ratemaking as a variation on the financial theme of uncertainty. As a matter of law, this Essay describes legal principles guiding the regulatory determination of the rate of return on utility property. It analyzes two valuation methods derived from the 1923 Bluefield Water Works decision (“attracting capital” and “comparable earnings”), as well as a third approach based on the capital asset pricing model. Discretionary elements in rate regulation make it impossible to wholly alleviate uncertainty in the pricing of infrastructure. Rate regulation therefore constitutes a speculative undertaking in its own right.

I. The Greatest Machine Ever Built

In a “world lit by lightning,” “time is the longest distance between two points.”¹ As Anthropocene excesses darken humanity’s prospects,² technological innovation strives to keep humans lit, warm, and connected. Law may not physically prepare the world for climate change, but it can dictate how low- and zero-carbon electrical infrastructure will be financed. This Essay analyzes public utility regulation as an application of financial economics.

The electrical grid that illuminates the world deserves nearly every superlative used to describe it. The electrical power system has been hailed as the “supreme engineering achievement of the 20th century,”³ the “world’s biggest, most complex machine,”⁴ and perhaps even “the most complex machine ever made.”⁵ Electricity can neither “be stored on any significant scale” nor be directed in the fashion of “classic switched networks.”⁶ Base load generation remains necessary because humans demand electricity precisely when solar

energy, arguably the greatest ecosystem service,⁷ is unavailable.⁸ By balancing generation and load “in real time,” the “sophisticated systems” that “ensure continuous delivery of reliable electric service”⁹ represent “the ultimate ‘just-in-time’ manufacturing process, where supply must be produced to meet demand in real time.”¹⁰

The American economy depends on electrical infrastructure,¹¹ the operation of “millions of component parts and individual devices . . . in ‘electromagnetic unity.’”¹² Engineering challenges will become more formidable as climate change forces the electrical system to adopt low- or zero-carbon sources of generation. The precise “mix of technologies, practices, and behaviors [that] will deliver substantial decarbonization” remains shrouded in “significant uncertainty.”¹³ Contributions by distributed generation,¹⁴ electrical storage,¹⁵ nuclear energy,¹⁶ and carbon capture and storage¹⁷—to name only four possibilities—elude precise quantification.¹⁸ Even the best established of these prospects, nuclear energy,¹⁹ requires “enormous facilities with high construction

Comm'n, Aug. 1, 2016) (discussing “zero-emissions nuclear generation resources as a bridge to the clean energy future” where “50% of New York’s electricity is to be generated by renewable sources by 2030 as part of a strategy to reduce statewide greenhouse gas emissions by 40% by 2030”).

costs.”²⁰ A future low- or zero-carbon electrical system “will have a higher capital intensity.”²¹

Maintaining the grid, let alone decarbonizing it, poses more than merely technological obstacles. Ensuring a constant flow of electricity also presents great challenges to law and finance. “[A]ny electricity that enters the grid immediately becomes a part of a vast pool of energy that is constantly moving in interstate commerce.”²² As public utility law continues its “great transformation,”²³ its “creative force” will compel us “to transform the most complex machine ever built into something vastly cleaner, more distributed, and more interactive.”²⁴

The law of regulated industries endeavors to lay the foundations of civilization—or at least to finance the most ambitious forms of infrastructure. Through Gilded Age legislation addressing industries “affected with a public interest,”²⁵ the law of regulated industries has built “intricate and pervasive systems which furnish light, heat, power, water, transportation, and communication.”²⁶ For an ambitious society seeking to “catch the last subway, the streetcar, the bus,” “[o]ne job is not enough, one life is not enough.”²⁷ As the legal basis of “Infrastructure U.S.A.,” public utility law has permitted “a degree of experimentation in governmental direction of economic activity . . . beyond any historical parallel.”²⁸

This Essay explains the obligation to ensure “just and reasonable” regulatory rates as a specialized application of financial economics. Ratemaking represents a legal exercise in capital asset pricing. Part II describes ratemaking as a variant of financial uncertainty. Part III reviews the law governing the rate of return on utility property. Part IV analyzes two valuation methods derived from the *Bluefield Water Works* decision (“attracting capital” and “comparable earnings”).²⁹ Part V presents a third approach based on the capital asset pricing model. Part VI concludes that discretionary elements in rate regulation make it

impossible to wholly alleviate uncertainty in utility pricing. Rate regulation therefore constitutes a speculative undertaking in its own right.

II. Ratemaking as Regulatory Asset Pricing

A. “Public” Utilities, Private Investors

Rate regulation is properly understood as a branch of public finance. The law of regulated industries, like taxation, not only “defray[s] the cost of services” that “the market would not provide in the desired quantity and at the desired price,” but also “transfer[s] money” between groups.³⁰ Differences between “public ownership” and “profit-seeking management” have predictable, systematic “effect[s] on the price behavior of government firms.”³¹ Public intervention in energy, transportation, and communications markets should be treated as instances of the Modigliani-Miller theorem.³² Capital structure—implemented through debt, preferred stock, and common stock³³—is merely a theoretical abstraction that arranges the order of claims against a firm without affecting fundamental valuation.³⁴

In the United States, most “networks that distribute products or services over geographic space” are owned by private investors and operated for profit.³⁵ Investor-owned utilities comprise three-quarters of America’s trillion-dollar electrical power system.³⁶ Extensive private ownership converts the term “public utility” into an egregious misnomer. Utilities are “public” in the pragmatic sense that they satisfy mass needs, like “traditional governmental functions of police and justice,” and do not become “less so when these services are rendered by private enterprise.”³⁷

From a global perspective, it is “striking that the United States was the only country that was able to maintain private ownership of most of its utilities

throughout the twentieth century.”³⁸ Other countries typically commit infrastructure to the public sector. As countries grow, utilities often draw hostile attention as “the first nationally prominent big businesses to emerge” from an industrial revolution.³⁹ The United States has eluded these political dynamics. True to an “energetic and articulate” culture that champions capitalism over socialism with “remarkable” intensity,⁴⁰ America embraces private ownership of infrastructure.

A mostly private electrical power system may struggle to replace climate-altering fuels. As commentators have noted, to “limit[] the anthropogenic increase in global mean surface temperature to less than 2 degrees Celsius,” the United States must reduce its greenhouse gas “emissions 80% below 1990 levels by 2050.”⁴¹ “[C]urrent wholesale power markets . . . appear limited in their ability to support investments in large, capital-intensive, low-carbon generation facilities such as nuclear or coal plants with carbon capture and storage.”⁴² The transition “to an 80 percent renewables future will require investing roughly \$50-70 billion per year over the next decade,” perhaps “between \$100 and \$200 billion per year as we approach 2050.”⁴³ Low-carbon conversion will demand sums “roughly two to five times larger than current levels of investment in new transmission and generation assets.”⁴⁴

The “higher capital intensity of a low-carbon electricity system,” relative to “the current fossil-based system,” compounds the risk inherent in “the long-lived nature of many of these assets.”⁴⁵ Even more than economies of scale⁴⁶ or scope,⁴⁷ the asset-specificity of “durable and immobile investments” is “the defining characteristic[] of infrastructure monopolies.”⁴⁸ Whether limited by geography, time, or embedded human capital, investments sunk into assets specific to one transaction can be neither recovered nor transferred.⁴⁹ Scale,

durability, and specialization all exacerbate the vulnerability of infrastructure to opportunism—by suppliers, customers, competitors, and the government.⁵⁰

Extensive historical investments in infrastructure represent sunk costs in a technologically dynamic marketplace responding exclusively to current costs.⁵¹ Economic theory prescribes a crisp response to sunk costs: Ignore them. Though sunk costs “are usually visible, . . . they should always be ignored when making economic decisions.”⁵² Economists evaluate cost on a wholly prospective basis;⁵³ costs already incurred “do not affect decisions on price and quantity.”⁵⁴

Heavy reliance on technological innovation in industries such as broadband communications and the post-carbon electrical system⁵⁵ demands a focus on “forward-looking costs” to the exclusion of “historical, booked costs” allegedly stranded by economic, technological, or regulatory change.⁵⁶ Whatever their legality,⁵⁷ legislative and administrative efforts to recover “stranded” investments are the economic “antithesis of competition.”⁵⁸

But today’s forward-looking investments are tomorrow’s sunk costs.⁵⁹ The prospect that infrastructure may be stranded by technological or political change affects the marginal propensity to invest. One prime example is the prospect that keeping the anthropocentric contribution to global temperatures below 2°C will “eliminat[e] virtually all natural gas use by 2050.”⁶⁰ The theory of contestable markets, a description covering vast turf between perfect competition and natural

monopoly,⁶¹ recognizes that sunk costs can impede future entry.⁶² Because an “investment that cannot easily be moved elsewhere is an impediment to exit,” sunk costs pose “a prime obstacle to entry.”⁶³

“Hit-and-run” entry in contestable markets, where investments are not irretrievably committed, imposes competitive discipline and relaxes the need for regulatory intervention.⁶⁴ Outside structurally contestable industries such as transportation and mobile telecommunications,⁶⁵ however, incumbents defend sunk investments through “sit-and-gun” behavior, including predatory pricing.⁶⁶

Sunk costs and contestable markets are ideas drawn from microeconomics and from industrial organization.⁶⁷ The principle of “costly reversibility” translates these ideas into corporate finance. Reversals of investment in physical⁶⁸ and human⁶⁹ capital are never free. “Costly reversibility implies that firms face higher costs in cutting than in expanding capital.”⁷⁰ The reluctance to build irretrievably sunk infrastructure, to say nothing of private investors’ recalcitrance to invest absent reassurance that they will recover their capital, represents a special case of costly reversibility.

The decarbonized future therefore requires not only technological but also legal and financial ingenuity. Investment risk of this magnitude poses financial

challenges beyond the conventional regulatory toolkit.⁷¹ Takings cases barring allegedly “confiscatory ratemaking”⁷² can do no more than “prevent governmental destruction of existing economic values.”⁷³ The confiscatory ratemaking concept “cannot be applied to insure values, or to restore values that have been lost by the operation of economic forces.”⁷⁴ Absent some mechanism for “socializ[ing] the costs of . . . investments” in low-carbon generation, “whether through rates, subsidies or some combination,” private investors “are unlikely to provide financing on favorable terms.”⁷⁵ Alarmingly, “liberalized electricity markets” may be incompatible with a low-carbon future.⁷⁶

To the extent that governments build or own infrastructure, regulatory pricing principles will also control. Rate regulation governs public and quasi-public enterprises, such as the Postal Service⁷⁷ and the Bonneville Power Administration.⁷⁸ Publicly owned elements of tomorrow’s zero-carbon electrical system will surely be priced “with a view to encouraging the widest possible diversified use of electric power at the lowest possible rates to consumers.”⁷⁹ Within any system of public finance seeking to spur growth,⁸⁰ especially one heeding the “golden rule” that government borrowing should never exceed net capital formation,⁸¹ balancing private and public investment will prove crucial to stabilizing rates of return.⁸²

The 2016 Supreme Court case of *Hughes v. Talen Energy Marketing, LLC*⁸³ limited states' efforts to promote the construction of generation capacity by promising rates more generous than those available in the federally regulated interstate wholesale market.⁸⁴ *Hughes* cabined states' freedom to "compel[] participants in a federally regulated marketplace to transact capacity at prices other than the price fixed by [that] marketplace."⁸⁵ The Court, however, conspicuously withheld judgment on other methods for encouraging "new or clean generation, including tax incentives, land grants, direct subsidies, construction of state-owned generation facilities, or re-regulation of the energy sector."⁸⁶ Environmental regulation and subsidies would compound the already difficult task of matching prices for electricity to the cost of generation, transmission, and distribution.⁸⁷

The balance of Part II will treat the valuation of utility property as a variant of a pervasive financial problem: investment under uncertainty.

B. A Generalized Model of Financial Uncertainty

1. Information Uncertainty

Prices are signals. They communicate pivotal information about cost, supply, and demand within "the central nervous system of the economy."⁸⁸ The discovery and dissemination of economic knowledge inform a collective "wisdom of prices."⁸⁹ What is true of prices on utility services is likewise true of the prices of those companies' shares, from individual trades⁹⁰ to market-wide demand.⁹¹ Even while invalidating state-level efforts to spur construction of

generating capacity, federal courts acknowledge that anticipated electrical sales revenue drive decisions to build (or retire) plants.⁹²

The valuation of investor-owned utilities therefore demands the proper setting of utility rates. “[C]apital-intensive” utilities historically supported regulation so that they could “secure capital on favorable terms” rather than “rely[ing] . . . on long-term debt financing” to “finance new capital investment” that neither “the equity markets” nor “annual cash flow” would support, at least absent “guaranteed rates and protected franchises.”⁹³ The price at which utilities can secure capital assumes greater importance in an industry that anticipates expensive low- and zero-carbon generation.

Finance is the branch of economics that analyzes the market for capital for speculative undertakings.⁹⁴ An efficient capital market rewards the assumption of risk with returns.⁹⁵ The expectation that the equity market’s excess return over a risk-free asset “should vary positively and proportionately to market volatility” represents the “first law of finance.”⁹⁶ As the Supreme Court has recognized: “The less risk, the less right to any unusual returns upon [an] investment[.]”⁹⁷ Economic theory anticipates the fundamental problem of utility law: finding ways to “provide sufficient incentives for long-term investments in capacity.”⁹⁸

“[E]very financial model” begins with “the uncertainty facing investors, and the substance of every financial model involves the impact of uncertainty on the behavior of investors and, ultimately, on market prices.”⁹⁹ Trouble arises in the zone of “[t]rue uncertainty,” where “risks are not well understood, where the range of outcomes is potentially very large, and where probabilities cannot be assigned with confidence.”¹⁰⁰ The distinction between quantifiable risk and wholly unknowable uncertainty, first recognized by Frank Knight and John

steeper toll on the downside.¹¹² Economic retrenchment necessarily reduces the rate at which business activity transmits economic information.¹¹³

“[P]eople prefer to act on known rather than unknown or vague probabilities.”¹¹⁴ When informational “quality is difficult to judge, investors treat signals as *ambiguous*.”¹¹⁵ As informational ambiguity amplifies uncertainty over the probability and magnitude of default outcomes, including the deadweight cost of bankruptcy, all premiums associated with bearing risk rise sharply.¹¹⁶

Information uncertainty confounds valuable signals with noise:

Theoretically, an observed signal (s) is characterized as a firm’s fundamental value (v), such as future cash flow or dividend, plus a noise term (e), that is, $s = v + e$. The variance of this signal measures information uncertainty: $\text{var}(s) = \text{var}(v) + \text{var}(e)$, where $\text{var}(v)$ is a firm’s underlying fundamental volatility and $\text{var}(e)$ reflects the quality of information.¹¹⁷

This passage describes two formulas:

1. An economic signal (s) is the sum of value (v) and noise (e): $s = v + e$
2. The variance of that signal is the sum of the variance of value and the variance of noise. Equivalently, the variance of a signal consists of quantifiable risk plus a premium attributable to the reliability of information used to quantify risk: $\text{var}(s) = \text{var}(v) + \text{var}(e)$

Both formulas find ready expression within rate regulation as an applied branch of financial economics. $s = v + e$ describes the utility’s value as a function of economic fundamentals, such as anticipated cash flow from utility operations. $\text{var}(s) = \text{var}(v) + \text{var}(e)$ indicates that variance in earnings comprises both fundamental variance and an additional premium reflecting uncertainty.

The reaction of investors to uncertainty deeply affects asset prices. “When agents are unsure of the correct probability laws governing the market return,” “they demand a higher premium to hold the market portfolio.”¹¹⁸ The following equation expresses the relationship between risk and uncertainty¹¹⁹:

112. Cf. *United States v. Butler*, 297 U.S. 1, 82 (1936) (Stone, J., dissenting). (“Threat of loss, not hope of gain, is the essence of economic coercion.”).

119. *Id.*

$$E_t r_{e,t+1} = \gamma V_t + \theta M_t$$

where E designates the expectation operator, r_e is the excess return of the market over a risk-free asset, V “is the conditional volatility of the market,” M “measures the amount of uncertainty in the economy,” t indexes all variables (and the expectation operator) over time, and coefficients γ and θ indicate aversion to risk and uncertainty.¹²⁰ Notably, this formula implies that “both risk and uncertainty carry a positive premium.”¹²¹ $E_t r_{e,t+1} = \gamma V_t + \theta M_t$ therefore represents a special case of $\text{var}(s) = \text{var}(v) + \text{var}(e)$.

Bifurcating $s = v + e$ and $\text{var}(s) = \text{var}(v) + \text{var}(e)$ will prove useful in evaluating economic signals whose underlying variability arises from distinct sources, one of which is less quantifiable and therefore more uncertain. Utility-owned infrastructure is rife with uncertainty. New electrical infrastructure designed to mitigate global climate change illustrates the impact of uncertainty on utility finance. Uncertainty along nearly every dimension—scientific, technological, economic, and political—would raise the cost of capital for any private investment. The ability to express and measure distinct sources of risk and uncertainty, each with its own quantitative traits (including the impossibility of reliable quantification under current data and methods), will prove useful in evaluating the impact of rate regulation on utility valuation and access to capital.

2. Risk-Neutrality and Irreversibility

A project as ambitious as electrical de-carbonization also illustrates the interaction of uncertainty with asset-specificity and sunk costs. Kenneth Arrow’s contributions to the risk-adjusted evaluation of public investments provide a useful starting point.¹²² Treating public ownership as the legal default sets a comparably neutral economic baseline. Municipal ownership accounts for one-fifth of America’s trillion-dollar electrical power industry¹²³ and remains a viable alternative to private ownership.¹²⁴

Because “the risks associated with a public investment are publicly borne, the total cost of risk-bearing is insignificant.”¹²⁵ Spreading “risk among all taxpayers” renders “negligible” the “costs of risk-bearing.”¹²⁶ The resulting risk-adjusted return may be higher than the private-sector equivalent,¹²⁷ more so if risk aversion among shareholders or managers raises a private firm’s cost of risk-bearing.¹²⁸ According to Arrow’s 1970 work with Robert Lind, “the government should ignore uncertainty in evaluating public investments.”¹²⁹

In terms of uncertainty within the variability of an economic signal, $\text{var}(s) = \text{var}(v) + \text{var}(e)$, the public sector’s unmatched ability to spread risk reduces risk-bearing cost—and any uncertainty associated with that exercise in risk management—to zero. Variability in the signal collapses to variability in fundamental value: $\text{var}(s) = \text{var}(v)$. Even more significantly, expected return on public investment becomes the lone measure of value: $s = v$.¹³⁰

Befitting an intellectual era that inspired intertemporal asset pricing¹³¹ and sustainability in resource economics,¹³² Arrow did not ignore intergenerational differences in “the revealed preference of individuals.”¹³³ In 1974 work with Anthony Fisher, Arrow recognized limits on “the evaluation of benefits from more traditional public investments.”¹³⁴ Risk-neutrality collapses if public investment “involves some irreversible transformation of the environment [effecting] a loss in perpetuity . . . and if information about the costs and benefits” changes future “expected values.”¹³⁵

Arrow and Fisher’s exception to risk-neutrality finds strong legal parallels. The National Environmental Policy Act demands that environmental impact statements report “any irreversible and irretrievable commitments of resources.”¹³⁶ The Endangered Species Act limits federal agencies’ “irreversible

or irretrievable commitment of resources.”¹³⁷ Although Arrow and Fisher contemplated irreversible events such as “the extinction of a form of life, . . . the destruction of a unique geomorphological phenomenon,” or the introduction of nonbiodegradable stock pollutants, their observations “about uncertainty, information, and irreversibility” apply generally, “without reference to environmental effects.”¹³⁸

Arrow and Fisher anticipated “cumulative ‘macro’ environmental effects, such as the increasing concentration of carbon dioxide in the global atmosphere, with its attendant climatic changes.”¹³⁹ Pending ecological catastrophe invites even more aggressive applications of uncertainty. At the most extreme, the “dismal theorem” undermines all attempts at coherent forecasting. “[T]he expected loss from [extraordinary] risks such as climate change is infinite.”¹⁴⁰ Under such extreme conditions, “standard economic analysis cannot be applied.”¹⁴¹ The “catastrophe-insurance aspect of . . . a fat-tailed unlimited exposure-situation . . . can dominate the social-discounting aspect, the pure-risk aspect, and the consumption-smoothing aspect.”¹⁴²

Unlike the basic Arrow-Lind theorem, Arrow and Fisher’s emphasis on irreversibility assigns maximum value to uncertainty. Within the basic specification of an economic signal’s variability, $\text{var}(s) = \text{var}(v) + \text{var}(e)$, these theoretical frames assume that $\text{var}(e)$ is much greater than zero. At levels less apocalyptic than those characterizing the dismal theorem (which effectively assumes that $\text{var}(e)$ approaches infinity), uncertainty may be modeled as the volatility of certain fundamental measures (such as growth in cash flow or dividends), conditioned on a time-varying measure of aversion.¹⁴³ Markets with indeterminate variance¹⁴⁴ are sometimes modeled according to stable

distributions,¹⁴⁵ despite their mathematical intractability and poor empirical fit.¹⁴⁶ Using the variance risk premium¹⁴⁷ as a proxy for uncertainty may explain risk factors known by names¹⁴⁸ such as jump risk,¹⁴⁹ tail risk,¹⁵⁰ and rare disaster risk.¹⁵¹

This account of uncertainty connects the environmental economics of irretrievably committed resources with sunk costs in microeconomics, the theory of contestable markets in industrial organization, and costly reversibility in finance. Pairing this narrative with expressions for individual components of economic signals and for variability in those signals provides a generalized framework for evaluating regulatory uncertainty. Especially for industries such as a future zero-carbon electrical system, these insights portend “a relatively high cost of capital” and “very challenging” financial issues for industries facing “large, capital-intensive” investments, “long time horizons” and “uncertainty regarding performance, future prices, and regulations.”¹⁵² To ground those potentially grave implications in legal principles, I now discuss the regulatory determination of return on utility assets.

III. Conventional Rate of Return Determinations

A. Cost-of-Service Ratemaking

The task of price regulation at “the heart of public utility regulation” has drawn deep scorn.¹⁵³ “The Supreme Power who conceived gravity, supply and demand, and the double helix must have been absorbed elsewhere when public utility regulation was invented.”¹⁵⁴ Rate regulation has earned opprobrium as

“the most speculative undertaking . . . in the history of [Anglo-American] jurisprudence.”¹⁵⁵

But ratemaking is neither lawless nor incoherent. Although courts today do not bind ratemaking agencies to “any single formula or combination of formulae,”¹⁵⁶ stable patterns have emerged. Admittedly, neither the Fourteenth Amendment nor the statutory “just and reasonable” ratemaking standard has enacted discounted cash flow analysis, the efficient market hypothesis, or capital asset pricing.¹⁵⁷ Those are the terms, however, by which rate regulation has priced utility services and shaped demand for utility stock.

Ratemaking traces its roots to the Supreme Court’s 1898 decision in *Smyth v. Ames*.¹⁵⁸ *Smyth* is simultaneously celebrated and derided for its declaration that “the basis of all calculations as to the reasonableness of . . . rates to be charged by a [public utility] must be the fair value of the property being used by it for the convenience of the public.”¹⁵⁹ To clarify this baffling formula, the Court offered a list of factors: “the original cost of construction, the amount expended in permanent improvements, the amount and market value of [utility] bonds and stock, the present as compared with the original cost of construction, the probable earning capacity of the property . . . and the sum required to meet operating expenses.”¹⁶⁰

Smyth prescribed rates according to “the cost of providing the service” rather than “some other basis,” especially “demand for the service.”¹⁶¹ In defending a competing definition of cost as the historic sum of prudent investments, Justice Brandeis restated *Smyth* as encompassing “not only operating expenses, but also capital changes” covering “interest, for the use of the capital; . . . [an] allowance for risk incurred; and enough more to attract capital.”¹⁶² Any rate that gives the utility “the opportunity to earn the cost of . . . service” should be deemed “constitutionally compensatory.”¹⁶³

Subsequent “methodology for establishing the cost of providing [utility] service” followed “a formula implicit in the *Smyth* opinion”.¹⁶⁴

$$RR = r \cdot B + OC + T$$

where

RR: revenue requirement

R: rate of return

B: rate base

OC: operating costs

T: taxes

Although all of these variables spark ratemaking disputes,¹⁶⁵ the “cost of common equity is frequently . . . a point of contention.”¹⁶⁶ Among the three elements of a regulated firm’s cost of capital (long-term debt, preferred stock, and common stock),¹⁶⁷ the rate of return on equity is often most fiercely contested, not least because that factor dictates market capitalization. Return on equity must be “sufficient to assure confidence in the financial integrity of the enterprise.”¹⁶⁸ Focusing on theoretical implications for regulatory economics, Part III now evaluates judicial standards for determining the cost of equity.

Smyth’s fair value standard faltered in practice. “In theory the . . . fair value standard mimics the operation of the competitive market,” inasmuch as “investments [whose] benefits exceed their costs . . . reward [utilities] with an

opportunity to earn an ‘above-cost’ return.”¹⁶⁹ Fair value demanded consideration of prevailing prices and wages, as well as “an honest and intelligent forecast as to probable price and wage levels during . . . the immediate future.”¹⁷⁰ At its most speculative, fair value emboldened a prediction, based on “judicial notice of the fact that there ha[d] been no substantial general decline in the price of labor and materials” for roughly a dozen years, that prices would not be “likely to decline within . . . one, two, or three years.”¹⁷¹ Within three years of this November 22, 1926, declaration, the stock market crash of October 1929 triggered the Great Depression.

As the Supreme Court later observed with respect to taxation, “the Constitution [does not] tolerate any result, however distorted, just because it is the product of a convenient mathematical formula.”¹⁷² Practical difficulties plagued the valuation of property whose owners bore legal obligations unique to their industry.¹⁷³ Justice Brandeis defended his “prudent investment” rule as an administratively convenient alternative to the “laborious and baffling task of finding . . . present value” for utilities “not commonly bought and sold in the market.”¹⁷⁴

Commentators likewise condemned *Smyth* as “rest[ing] upon a giant illusion.”¹⁷⁵ Even courts recognizing that “value depends upon the earnings” foolishly “insist[ed] that the vicious circle involved (in basing the earnings on the value) can be escaped merely by the simple expedient of measuring the value of replacement cost.”¹⁷⁶ The entire enterprise, which *Smyth* called an “embarrassing question,”¹⁷⁷ ranked “among the great juristic myths of history with the Law of Nature and the Social Contract.”¹⁷⁸ By 1944, the Supreme Court capitulated: “rates cannot be made to depend upon ‘fair value’ when the value of the going enterprise depends on earnings under whatever rates may be anticipated.”¹⁷⁹

B. Bluefield's Two Standards

But three weeks after Justice Brandeis proposed prudent investment as an alternative to *Smyth's* fair value standard, the Supreme Court provided further guidance on determining the rate of return,¹⁸⁰ which remains good law, notwithstanding the Court's later embrace of prudent investment as a permissible (but not required) basis for valuation.¹⁸¹

Bluefield prescribed not one but two sets of guidelines. The first, the "comparable investment" rule, promised "such rates as will permit" the utility "to earn a return . . . equal to that generally being made at the same time and in the same general part of the country on investments in other business undertakings which are attended by corresponding, risks and uncertainties," but not the return "anticipated in highly profitable enterprises or speculative ventures."¹⁸²

Bluefield's second approach prescribes rates "reasonably sufficient to assure confidence in the financial soundness of the utility" and "adequate . . . to maintain and support its credit and enable it to raise the money necessary for the proper discharge of its public duties."¹⁸³ Utilities must earn returns sufficient to "attract capital" and "compensate investors for the risks assumed."¹⁸⁴ Rates that "compensate[] investors" and "attract capital" should cover "operating expenses, debt service, and dividends."¹⁸⁵

Three years before the Supreme Court directly addressed the issue, Learned Hand anticipated the congruence of *Bluefield's* two standards. "The recurrent appeal to a just rate and a fair value," he wrote, "involves a tacit comparison of the profit under the rate with profits available elsewhere; i.e., under those competitive enterprises which offer an alternative investment."¹⁸⁶ Judge Hand's

186. *Consol. Gas Co. v. Newton*, 267 F. 231, 236 (S.D.N.Y. 1920).

“statement of the comparable-earnings standard” recognized that “attracting capital” requires offsetting the opportunity cost of alternative investments.¹⁸⁷

Judge Hand and *Bluefield* reflected the modern understanding of opportunity cost as “the cost associated with opportunities that are forgone by not putting [a] firm’s resources to their best alternative use.”¹⁸⁸ Opportunity cost offsets the behavioral impact of sunk cost.¹⁸⁹ Whereas sunk cost is “usually visible” but “should always be ignored,” opportunity cost “is often hidden” but must always “be taken into account.”¹⁹⁰ Irrational consideration of sunk costs often prompts conduct based on previous investment.¹⁹¹ Agents are sometimes “too much invested to quit.”¹⁹² Regulatory accounting should not compound such irrationality.

Bluefield’s “two conceptions are obviously intertwined.”¹⁹³ Proper understanding of the regulatory rate of return begins more intuitively with a firm-specific focus on the conditions that would induce investors to bypass other options. Justice Brandeis recognized that a continuous “inflow of [new] capital” into a regulated firm “can only be assured by treatment of capital already invested,” so that fairness toward existing investors “will invite and encourage further investment.”¹⁹⁴

Bluefield’s two standards coexist today alongside a model derived from corporate finance. Parts IV and V will examine all three models.

IV. Regulatory Asset Pricing After *Bluefield*A. *Attracting Capital*

1. Discounted Cash Flow

A 1991 D.C. Circuit case, *Tennessee Gas Pipeline Co. v. FERC*,¹⁹⁵ illustrates pitfalls in determining a return sufficient to attract capital. In setting gas pipeline rates under section 4 of the Natural Gas Act,¹⁹⁶ FERC reasoned “that investors are not able to account fully for the effects of a decline in interest rates on their investment alternatives until some six months or more after those rates are published.”¹⁹⁷ That assertion invited withering scrutiny of FERC’s discounted cash flow (DCF) methodology.

“DCF analysis” assumes “that the price of a stock is the current value of all expected future cashflows, discounted at the rate of return.”¹⁹⁸ DCF assumes that the price of stock equals the present value of a company’s dividend stream, projected to grow at a constant rate.¹⁹⁹

$$P_0 = \frac{D_1}{r - g}$$

where

P_0 : Today’s price

D_1 : Next year’s dividend

r : Rate of return

g : Rate of growth

Solving for r , the rate of growth, yields $r = D_1/P_0 + g$. That “key equation . . . employs the current price of the utility, because price is understood to represent the best possible assessment of . . . available information.”²⁰⁰

Discounted cash flow analysis enjoys a prominent role in utility economics.²⁰¹ In 1966, Lionel Thatcher proposed that the Federal

200. *Tenn. Gas*, 926 F.2d at 1210.

201. See, e.g., *General Tel. Co. v. Iowa State Commerce Comm’n*, 275 N.W.2d 364, 369 (Iowa 1979); *New England Tel. & Tel. Co. v. Pub. Utils. Comm’n*, 390 A.2d 8, 36 (Me. 1978).

Communications Commission adopt an earnings-price model identical to the DCF model in *Tennessee Gas*.²⁰² Because the simple ratio of earnings to price allegedly “understate[d] true capital costs by failing to account for investor expectations of future growth,” Thatcher proposed “a ‘growth factor’ determined by the ratio of dividends to the book value of stock adjusted for growth.”²⁰³

In his final scholarly work before being appointed to the D.C. Circuit, Harold Leventhal recognized that “it is mathematically sound”—albeit with “simplifying assumptions”—“to express the capital attracting rate for equity as equal to . . . [the] dividend-price ratio . . . plus the anticipated growth rate in earnings per share.”²⁰⁴ $r = D_1/P_0 + g$ “is a tautology,” Leventhal admitted.²⁰⁵ “[B]ut it is a correct tautology.”²⁰⁶

2. Gordon Growth Model

The Gordon growth model describes stock prices as a function of dividends and dividend growth rates:²⁰⁷

$$P = \frac{D(1+g)}{r + \pi - g}$$

where r is the risk-free rate, P is the stock price, D is the current dividend, g is the expected rate of dividend growth and π is the equity risk premium.²⁰⁸ The Gordon growth model holds even when interest rates, growth rates, and the risk premium change,²⁰⁹ provided that “the long-run growth rate, g , is . . . interpreted as a weighted average of expected future growth rates.”²¹⁰ Holding the equity risk premium to zero and redefining $D(1+g)$ as a forward-looking dividend— $D(1+g) = D_1$ —reveals the DCF formula in *Tennessee Gas* as a special case of the Gordon growth model:

$$P = \frac{D(1+g)}{r + \pi - g} \leftrightarrow P_0 = \frac{D_1}{r - g} \because \pi = 0, D_1 = D(1+g)$$

210. See Boyd et al., *supra* note 208, at 660.

Further simplification may be achieved by holding dividend growth to zero. In that event, the rate of return is simply the ratio of forward-looking dividends to current stock price.²¹¹

$$r = \frac{D_1}{P_0} \therefore P_0 = \frac{D_1}{r}$$

The simple ratio of earnings to stock price “generat[es] that level of earnings necessary to maintain the share price at the attributed rate base per share,” where investors will buy utility stock.²¹² Among other criticisms of a straightforward calculation of the “going rate of return . . . directly from the market evaluation of . . . utility stock,”²¹³ is the allegation that the earnings-price ratio “is particularly inapplicable to a new venture, whose observed stock price reflects anticipated rather than current earnings.”²¹⁴ Simple implementations of the Gordon growth model may not capture all macroeconomic factors affecting stock prices and firm valuations.²¹⁵

Its very simplicity, however, enables the Gordon growth model to accommodate numerous assumptions. Many authors “extend the simplest Gordon growth model to allow dividend growth rates to have several stages.”²¹⁶ Some models “permit[] growth firms to start with high dividend growth rates and then decelerate to a stable long-run rate.”²¹⁷ Others “propose random but independent dividend growth rates.”²¹⁸ One “variant of the Gordon growth model . . . us[es] the assumption that the log dividend price ratio follows a random walk”— $D_{t+1}/P_t = \exp(x_t)$, where $x_t = x_{t+1} + \varepsilon_t$ “denotes the log dividend-price ratio using a forward or indicated dividend rather than a historical dividend.”²¹⁹

Tennessee Gas represented a stark departure from established principles of discounted cash flow analysis and other dividend growth models. FERC's effort to defend "a 'pragmatic adjustment'" on the basis of an alleged "lag in the decline of dividend yields following [a] decline in interest rates" raised an "intolerable conflict with [DCF] principles."²²⁰ "Everything else being equal, a decline in interest rates means a decline in dividend yields, as stocks and bonds compete for investors' capital."²²¹ Declining rates drive capital from bonds into stocks, causing the price of utility stock to rise and its yield to drop.²²² Even sources cited by FERC identified utility stocks "as especially close substitutes of bonds" in light of "their (historically) low levels of risk" and similar sensitivity to interest rates.²²³

3. Efficient Market Hypothesis

Even more importantly, FERC's handling of interest-rate evidence, especially its "lag theory" of delayed investor reactions to interest-rate changes, constituted "a frontal assault on 'the cornerstone of modern investment theory,' the Efficient Market Hypothesis."²²⁴ The "strong" form of the efficient market hypothesis posits that security prices reflect all information, public and private, and that the prevalence of this knowledge prevents investors from earning excess returns.²²⁵ "[I]n an efficient market, there is no way for most investors to achieve consistently superior rates of return."²²⁶ Empirical measures of investment

outcomes suggest that efficient markets, even if not omniscient or frictionless, do eliminate excess returns, at least with respect to individual securities or other small samples.²²⁷

Even less stringent versions of the efficient market hypothesis bode ill for excess returns.²²⁸ The weak version posits that markets assimilate all public information.²²⁹ The semi-strong version assumes immediate diffusion of public information into security prices.²³⁰ Acceptance of the efficient market hypothesis in weak form eliminates excess returns from technical analysis.²³¹ The semi-strong version defeats fundamental analysis.²³² Disproving the presence of serial dependencies in security prices would confirm at least the weak hypothesis.²³³ By citing evidence that markets assimilated surprising news regarding the discount rate, money supply, inflation, and real economic activity within one day, *Tennessee Gas* acknowledged at least the weak form of the hypothesis.²³⁴

The law of regulated industries is likely to follow federal securities law. The “fraud on the market” rule presumes that “the market price of shares traded on well-developed markets reflects all publicly available information and, hence, any material misrepresentations,” and that the typical investor who trades at market price relies “on the integrity of that price.”²³⁵ In adopting the “fraud on the market” theory, the Supreme Court has “relied upon the ‘semi-strong’ version” of the efficient market hypothesis.²³⁶

L. 635, 640 & n.24 (2003); Fama, *Efficient Capital Markets: A Review of Theory and Empirical Work*, *supra* note 225, at 388).

Despite criticism that this presumption rests on unfounded acceptance of efficiency,²³⁷ the Supreme Court has declined to recognize “the kind of fundamental shift in economic theory that could justify overruling” the fraud on the market rule.²³⁸ The Court continues “to presume that most investors—knowing that they have little hope of outperforming the market in the long run based solely on their analysis of public available information—will rely on the security’s market price as an unbiased assessment of the security’s value in light of all public information.”²³⁹

These presumptions collide with more sophisticated understandings of investor heterogeneity and of limits on corrective arbitrage. A market “composed solely of information traders” is a market “where price efficiency and the CAPM hold” and where “[r]isk premia are determined solely by beta and distribution of returns on the market portfolio.”²⁴⁰ But markets host sentiment-driven noise traders as well as fully informed, rational traders.²⁴¹ As “noise traders weaken the relation between security returns and beta” and “create a positive conditional correlation between abnormal returns and beta,”²⁴² “steady and forceful” pressure upon “the twin paradigms of price efficiency and the CAPM” compels a “behavioral theory of capital asset prices.”²⁴³

The rise of indexes and index-based investing²⁴⁴ facilitates self-segregation among investors and information-gathering intermediaries.²⁴⁵ Even sophisticated agents exhibit herding behavior.²⁴⁶ Delays in the diffusion of

information affecting prices imply that some stock groups—including utility stocks as a distinct asset class—“incorporate new information at different rates.”²⁴⁷ Observed delays in the diffusion of information implies that noise trader risk diminishes the corrective potential of arbitrage.²⁴⁸

B. Comparable Earnings

One final aspect of *Tennessee Gas* offers insight into the relationship between *Bluefield's* attracting investment and comparable earnings standards. FERC relied exclusively on interest-sensitive “estimates of . . . [the] cost of equity capital.”²⁴⁹ FERC made no effort to “measure [the] industry rate of return or” the pipeline’s “relative risk within the industry.”²⁵⁰

But such evidence was available. Company-specific factors, beyond interest rate changes, might have reflect changes in business or financial risk affecting the utility’s cost of capital. “[C]ompany-specific risk” through a substantial increase in “the spread between Tenneco’s bond yields and the risk-free yield” indicated “that investors thought Tenneco was becoming riskier.”²⁵¹ Failure to address this evidence compounded FERC’s vulnerability,²⁵² particularly in light of precedent distinguishing purely interest-sensitive adjustments in regulatory rate-of-return determinations²⁵³ from the consideration of firm-specific factors affecting earnings or dividends.²⁵⁴

This aspect of *Tennessee Gas* clarifies the relationship between utility stock and the bond markets. The relevant corner of fixed-income markets is not Treasuries, but corporate bonds derided as “junk.”²⁵⁵ High-yield bonds correlate closely to equities and bear similar risks.²⁵⁶ Low-rated corporate debt with high

default risk exhibits informational efficiency similar to its issuer's stocks.²⁵⁷ High-yield bonds, coarsely speaking, are "equity in drag."²⁵⁸ More elegantly: "A low-grade bond can be viewed as a hybrid security consisting of a government bond and a claim on the issuing firm's equity."²⁵⁹

Decomposing return on utility stock into bond-like and equity-like components proves critical in explaining the relationship between *Bluefield's* "attracting investment" and "comparable earning" standards. According to Harold Leventhal's review²⁶⁰ of *Willcox v. Consolidated Gas Co.*,²⁶¹ Consolidated and its regulators had agreed "that the Constitution guaranteed" a "return available without risk, such as return from government obligations."²⁶² Treasury bonds as risk-free securities set a crucial benchmark in ratemaking and utility valuation.

Despite ultimately reversing, the Supreme Court adopted the economic analysis developed at trial. "One who invests his money in a business of a somewhat hazardous character" has "the right to a larger return, without legislative interference, than can be obtained from an investment in government bonds or other perfectly safe security."²⁶³ Beyond this baseline, regulation reduced "investment risk in a gas company . . . almost to a minimum."²⁶⁴ Equity in Consolidated, thanks to its lawful "monopol[y] [on] the gas service of the largest city in America," represented as "secure [an] investment as can be imagined with regard to any private manufacturing business."²⁶⁵

From *Willcox* to the 1968 *Permian Basin Area Rate Cases*,²⁶⁶ the comparable earnings standard displaced "earnings-price ratio computations."²⁶⁷ "[C]omparative risk analysis" can be based on statistical evidence that "the ratio of market price to book value of equity shares varies directly with positive risk (growth possibilities) and inversely with negative risk (possibility of a decline in

earnings and/or share price).”²⁶⁸ On these assumptions, “the proper rate of return is that which maintains the company’s market-book ratio on the same level as ‘alternative investment opportunities,’” such as indexes of utility companies.²⁶⁹

Financial data involving other companies exposed the comparable earnings standard’s conceptual weakness. *Permian Basin* “emphasiz[ed] . . . returns on equity earned by other gas companies” or even by oil producers, whose “revenues . . . were admittedly not regulated.”²⁷⁰ The very presence of rate regulation ensures “that there is no company precisely comparable.”²⁷¹ Either “the category of comparative firms is so broad that it includes firms in the unregulated sector,” or an exclusive focus on “regulated rates . . . in comparative-risk analysis” renders “the test . . . circular.”²⁷²

Nevertheless, market pricing of utility stock promises “a built in self-righting mechanism,” insofar as “changing interest rates or capital-scarcity conditions” will lead investors to “demand a greater or lesser return to hold the stock.”²⁷³ By displacing a solipsistic, firm-specific focus, comparable earnings approaches forced regulators to evaluate accounting-based assessments such as the prudent investment rule or DCF in light of government bonds yields and equity premiums for regulated and unregulated firms.

Before modern portfolio theory,²⁷⁴ “finance theory was little more than a collection of anecdotes, rules of thumb, and manipulations of accounting data.”²⁷⁵ The law of regulated industries anticipated two of the “most interesting applications of probability and optimization theory” in finance²⁷⁶: the efficient market hypothesis and the capital asset pricing model (CAPM). Part V now explores the CAPM and its application to rate regulation.

V. The Capital Asset Pricing Model

A. DCF and CAPM as Benchmarks Within a Zone of Reasonableness

Standard regulatory practice often deploys comparable earnings methodologies in tandem with DCF analysis to establish a “zone of reasonableness” for a utility’s “rate of return on equity.”²⁷⁷ Consistent with the

277. *Williston Basin Interstate Pipeline Co. v. FERC*, 165 F.3d 54, 57 (D.C. Cir. 1999); *accord* *N.C. Utils. Comm’n v. FERC*, 42 F.3d 659, 661-62 (D.C. Cir. 1994).

Gordon growth model, FERC's regulation of oil pipelines uses "a discounted cash flow . . . model" to "project[] investor growth expectations over the long term by adding average dividend yields to estimated constant growth in dividends over the indefinite future."²⁷⁸ FERC "then assigns the pipeline a rate within" the zone of reasonableness as determined by DCF "to reflect specific investment risks associated with that pipeline," relative "to a proxy group of publicly traded companies."²⁷⁹

Reference to a proxy group therefore performs the spatial equivalent of using "long-term growth projection[s]" to normalize distortions otherwise arising from exclusive reliance on "short-term data limited to a narrow segment of the economy."²⁸⁰ Short-term projections, *ceteris paribus*, are easier and more reliable.²⁸¹ But long-term projections hedge against "unanticipated developments" that may undermine shorter forecasts.²⁸² Checking financial information generated by comparable firms likewise sharpens DCF analyses based on one firm's earnings.

Before 1999, the Florida Public Service Commission supplemented two DCF models applied to a water utility index with two additional comparable earnings benchmarks.²⁸³ First, the PSC employed a "risk premium model applied to an index of publicly traded natural gas utilities" as a proxy for water and wastewater utilities with less ascertainable financial data.²⁸⁴ Second, the Commission used an asset pricing model based on the market return of dividend-paying stocks, the 30-year Treasury Bonds yield, and the average beta" of the water utility index.²⁸⁵

In 1999, Florida eliminated historical DCF in favor of "prospective, or forecasted growth rates" based on "the historical trend in dividends."²⁸⁶ The Commission also eliminated risk adjustments extrapolated from the gas industry, which it deemed "no longer a reasonable proxy."²⁸⁷ Critically, the Commission recognized that its "CAPM model, because it is a risk premium model, will appropriately reflect the direction of interest rates as previously indicated by the gas risk premium model."²⁸⁸ This use of the CAPM has become prevalent.²⁸⁹

B. A Formal Description of the CAPM

The CAPM remains the dominant paradigm in financial risk management.²⁹⁰ The development of “general models represent[ing] equivalent approaches to the problem of capital asset pricing under uncertainty” gave rise to today’s CAPM.²⁹¹

The capital asset pricing model boasts convenience and “seductive simplicity.”²⁹² The CAPM quantifies the premium for shouldering risk in an asset, over a benchmark represented by the return on a risk-free investment:

$$r_a = r_f + \beta_a(r_m - r_f)$$

where r_a , r_m , and r_f represent returns on the asset, the broader market and a risk-free investment, and where β_a represents the individual asset’s beta *vis-à-vis* the market portfolio.²⁹³

Rearrangement yields the following relationship:

$$r_m - r_f = \frac{r_a - r_f}{\beta_a}$$

The left side of this equation represents the *risk premium*,²⁹⁴ the difference between returns on an investment and the risk-free baseline.²⁹⁵ The risk premium dictates a firm’s cost of capital.

C. Beta

Beta provides the simplest measure of undiversifiable risk.²⁹⁶ It supplies information on volatility and liquidity in the broader marketplace. While measuring co-movement between a single security and the market as a whole, beta does not “assum[e] away the existence of interrelationships among securities,” but nevertheless “captures a large part of such interrelationships.”²⁹⁷

297. William F. Sharpe, *A Simplified Model for Portfolio Analysis*, 9 MGMT. SCI. 277, 281 (1963).

Beta of 1 indicates an asset whose sensitivity to risk is the same as the broader market's.²⁹⁸ Positive values for beta below 1 indicate an asset that moves in the market's direction, but is not as sensitive.²⁹⁹ Higher beta signals the need for a higher return to attract investment in a presumably riskier company.³⁰⁰

Beta is a measure of systematic covariance.³⁰¹

$$\beta_y = \frac{\text{cov}(x, y)}{\text{var}(x)} = \frac{\text{cov}(x, y)}{\sigma_x^2}$$

Beta reports the relationship between returns on a single asset and returns on the tradable universe.³⁰² Beta as correlated relative relativity is the product of (1) the ratio of asset-specific volatility to market-wide volatility and (2) the correlation between asset-specific and market-wide returns.³⁰³

$$\beta_a = \frac{\sigma_a}{\sigma_m} \rho(a, m) = \frac{\sigma_a}{\sigma_m} \cdot \frac{\text{cov}(a, m)}{\sigma_a \sigma_m} = \frac{\text{cov}(a, m)}{\sigma_m^2} = \frac{\langle (x_a - \mu_a)(x_m - \mu_m) \rangle}{\langle (x_m - \mu_m)^2 \rangle}$$

These elaborations of the CAPM make it easy to understand ratemaking as asset pricing. Specifically designating an index of water utilities as the target asset class yields a pricing model for water and wastewater utilities:³⁰⁴

$$r_u = r_f + B_u(r_u - r_f)$$

r_u : "Investor's required rate of return"

r_f : "Risk-free rate (Blue Chip forecast for 30-year Treasury bond)"

β_u : "Measure of industry-specific risk (Average for water utilities followed by *Value Lines*)"

r_m : "Market return"

The capital asset pricing model suffers from many weaknesses. Most critically, beta is not positively related to returns on stock.³⁰⁵ Returns are skewed³⁰⁶ and exhibit heavier than normal tails.³⁰⁷ Many risks follow abnormal, non-Gaussian distributions.³⁰⁸ Large swings of 3σ to 6σ occur so often that “[e]xtreme price swings are the norm in financial markets—not aberrations.”³⁰⁹ The maximum price change in the American stock market from 1871 to 2010 was “a ‘ten-sigma event,’” whose probability under “a normal distribution” would be “less than once in the life of the universe.”³¹⁰

But attacks on “standard deviation and its variations” as measures of risk in “non-normal distributions” have failed to dislodge beta,³¹¹ if only because “relatively little effort has been made” to devise “a better risk measure.”³¹² Beta’s leading nemesis has conceded that “market professionals (and academics) still think about risk in terms of market β .”³¹³ Even models purporting to deprecate beta as “insignificant” continue to treat beta as “an important explanatory variable,” despite refusing to treat beta as “the *main* explanatory variable.”³¹⁴

The CAPM thrives despite academic attacks. “It takes a better theory to kill an existing theory,” and finance has “yet to see [a] better theory.”³¹⁵ Empirical support for other asset-pricing models is not better and “the economic

importance of the empirical evidence against the CAPM . . . is ambiguous.³¹⁶ Courts continue to think of risk and asset pricing in terms of the CAPM.³¹⁷ The “concept of beta risk” represents “the single most important contribution of academic researchers” to finance.³¹⁸

VI. Utility Regulation as a Speculative Undertaking in Its own Right

The persistence of competing rules for utility valuation and rate-of-return determinations demonstrates the uncertainty inherent in regulation. “[N]either law nor economics has yet devised generally accepted standards”³¹⁹ Utility regulation “will always [raise] . . . embarrassing question[s]” of indeterminacy and inefficacy.³²⁰

Public utility law does bear an obligation to ensure an adequate return on private investment.³²¹ The investment-backed expectations of utility shareholders are based strictly on opportunity cost. “Any investor paying attention” to the law must “realize that he [cannot] rely indefinitely on traditional regulatory methods.”³²² “[R]egulatory measures are temporary expedients, not eternal verities.”³²³ Because the “Constitution does not bind rate-making bodies to the service of any single formula or combination of formulas,”³²⁴ regulated firms “have no vested interest in any particular [ratemaking] calculation.”³²⁵

Ratemaking principles require simply that the “determination of fair prices” be “based on reasonable financial requirements.”³²⁶

“[T]he notion of lawfulness requires . . . that the chosen framework” for rate regulation “not collapse in practice into a standard-less exercise of Commission discretion resting on no more than an assertion of ‘expertise.’”³²⁷ “[T]he principle that ‘lower is better,’” when presented as “an argument that seems to have no end and little connection to any stated purpose,” provides no basis for affirming a ratemaking decision.³²⁸ Regulators must justify any particular methodological choice as an “appropriate rate reduction measure.”³²⁹

Concededly, “a reviewing court must generally be at its most deferential” when an agency “is making predictions, within its area of special expertise, at the frontiers of science.”³³⁰ But review of administrative decisions routinely requires judges to “acquire the learning pertinent to complex technical questions in such fields as economics, science, technology and psychology.”³³¹ To leave all “to the skill of experts” is to deny that “[e]xpertise is a rational process and a rational process implies expressed reasons for judgment.”³³² Judges “should not automatically succumb” to regulators’ “acknowledged expertise . . . overwhelmed as it were by . . . utter ‘scientificity.’”³³³ “Restraint, yes, abdication, no.”³³⁴

Exclusive reliance on market forces abjures legal responsibility. “[T]he prevailing price in the marketplace cannot be the final measure of ‘just and reasonable rates . . .’”³³⁵ Having chosen to “subject[] producers to regulation because of anticompetitive conditions in the [gas] industry, Congress could not

have assumed that ‘just and reasonable’ rates could conclusively be determined by reference to market price.”³³⁶

The obligation to articulate some defensible basis for a rate finds parallels throughout the law of regulated industries. The power to “modify any requirement” of title II of the Communications Act³³⁷ did not include the requirement that carriers file tariffs,³³⁸ lest “a fundamental revision” create “a scheme of rate regulation only where competition does not exist.”³³⁹ To like effect is the admonition that a presumption of competition does not constitute regulation of entry in the public interest. “Merely to assume that competition is bound to be of an advantage, in an industry so regulated and so largely closed . . . is not enough.”³⁴⁰

Even broader legal consilience connects regulatory valuation to taxation. *Bluefield’s* two methods (comparable earnings and attracting investment) and Justice Brandeis’s prudent investment rule precisely parallel the three recognized methods for valuing real estate in *ad valorem* taxation.³⁴¹ Property taxation reveals the superiority of *Bluefield’s* standards over prudent investment. “[O]rdinarily the market data approach, guided . . . by actual buyers and sellers of comparable property in the market, is the best guide to market value.”³⁴² The “market price” from “a recent, voluntary, arm’s length transaction” between “knowledgeable and willing” parties supplies “very persuasive” if “not conclusive” evidence of value.³⁴³ The “income approach is the most effective approach in determining the value of investment properties,” especially “large office buildings.”³⁴⁴ “Finally . . . the cost approach is the least reflective of market value and is used only as a check of the estimates obtained from the other approaches.”³⁴⁵

At least in taxation, exactly three methodologies—comparable earnings, discounted cash flow, and accounting—appear to exhaust the universe of feasible approaches to valuation. All three approaches persist even as the valuation of real property and ecosystem services incorporates large datasets of economic and geographic information.³⁴⁶ The question is whether valuation methodologies in

utility regulation can exhibit greater creativity, especially as climate change exerts ever greater pressure on the electrical industry.

*CSX Transportation, Inc. v. Georgia Board of Equalization*³⁴⁷ illustrates the relationship between valuation standards in regulation and taxation. In *CSX*, an appraiser “used three different valuation techniques—the discounted cash-flow approach, a market multiple approach, and a stock and debt approach”—to derive estimates for railroad property “ranging from \$8.126 billion to \$12.346 billion.”³⁴⁸ These three approaches correspond to *Bluefield*’s attracting investment and comparable earnings standards and to the contemporary synthesis of these standards within the CAPM.

CSX hinged not on the validity of these methods, but on their application. The appraiser “subtract[ed] . . . \$400 million” from \$8.126 billion “to account for intangible property not subject to ad valorem taxation” and thereby “settled on \$7.8 billion as his final estimate.”³⁴⁹ Despite agreeing in principle with the state’s valuation methodology,³⁵⁰ the railroad valued its taxable property at \$6 billion.³⁵¹ Acknowledging “the variation in the state appraiser’s market value range,” to say nothing of the railroad’s competing estimate, the Supreme Court reasoned that “individual [valuation] methods yield sometimes more, sometimes less reliable results” and “can produce substantially different estimates.”³⁵²

In regulation as in taxation, the “admittedly complex” task of valuation “is at bottom just ‘an issue of fact about possible market prices.’”³⁵³ Courts “routinely” make “determinations of market value,” even “without the benefit of a market transaction.”³⁵⁴ Far from being a mechanical “matter of mathematics,” easily reviewed by “simply . . . doublechecking . . . equations,” calculating “true market value is an applied science, even a craft.”³⁵⁵ “To make a fetish of mere accounting is to shield from examination the deeper causes, forces, movements, and conditions which should govern rates.”³⁵⁶

356. *Fed. Power Comm’n v. Hope Nat. Gas Co.*, 320 U.S. 591, 643 n.40 (1944) (Jackson, J., dissenting).

Thoughtful comparison of *all* ratemaking methods—prudent investment, DCF, comparable earnings, and the CAPM—reveals critical differences along two dimensions. One dimension is *temporal*, running from the determinate (if imperfectly recorded or reported) past to an intrinsically uncertain future. Among standards for determining a utility's rate of return, the prudent investment standard alone connects future return to past expenditures. The Gordon growth model demonstrates how DCF analysis can be conducted on the basis of past dividends. But *Bluefield's* directive that regulators set return so as to “attract investment” spins the temporal arrow toward the future. As securities law warns, past performance is no guarantor of future performance, and future rather than past cash flow dictates stock prices.

The other dimension is economically *spatial*. The spatial boundary among rate-of-return methodologies falls along a different divide. The prudent investment and DCF methodologies are *firm-specific* insofar as they rely on economic performance unique to the regulated firm. The value of the comparable earnings standard lies in its directive that regulators look beyond the firm. Industry-wide information, so pivotal in the *Permian Basin Area Rate Cases*,³⁵⁷ represented a logical step toward the consideration of firm-specific, industry-specific, and market-wide information in ratemaking methodologies based on the CAPM.

Temporal and spatial differences in ratemaking methodologies will profoundly affect the pricing of future utility infrastructure under uncertainty. At this stage in the development of low- and zero-carbon electrical generation, regulators have a very limited set of antecedents. If regulation, like economics itself, is a system for conveying information through prices, then retrospective and firm-specific methodologies offer an initial but ultimately illusory advantage. Prudent investment or DCF analysis based on historical dividend information is almost surely more readily discovered, and with greater confidence, than inquiries into the regulated industry, capital markets, or macroeconomic conditions.

Trouble arises, however, upon the realization that *all* sources of uncertainty related to low- or zero-carbon electrical infrastructure—changes in climate, energy technologies, the nature of demand for electricity, and the law itself—are forward-looking. Only by striking a prospective perspective and expanding inquiry past firm-specific factors can regulators accurately forecast demand for electricity, its cost drivers, and the willingness of investors to shoulder complex sources of risk. Regulators have no choice but to climb the conceptual progression from forward-looking DCF analysis (using sophisticated variants of the Gordon growth model) to industry-wide or market-wide methodologies exploiting comparable earnings and CAPM data.

The bias against retrospective, firm-specific methodologies and in favor of prospective, spatially broader methodologies arose during *Hope Natural Gas*,

357. 390 U.S. 747 (1968).

the decision rightfully regarded as the genesis of contemporary regulation. Justice Robert Jackson, lauded for “analyz[ing] with particularity the economic and social aspects of natural gas as well as the difficulties which led to the enactment of the Natural Gas Act,”³⁵⁸ warned against unthinking endorsement of prudent investment methodology. Although “prudent investment” may boast “relative merits for a utility which creates its service merely by its investment,” that theory “has no rational application where there is no such relation between investment and capacity to serve.”³⁵⁹

Justice Jackson’s criticism supplies a standing admonition against backward-looking regulatory pricing. In forecasting demand for a utility service and the price at which investors will support entry, as with *all* forward-looking judgments, “there is little more relation between [past] investment and the results than in a game of poker.”³⁶⁰ Value is measured by what consumers will pay for the output of a business, “not by what [its owner] puts into it.”³⁶¹

Ratemaking amid technological turmoil and existential environmental angst reflects the challenge of investing as a speculative undertaking. All signals combine value and noise. $s = v + e$. Variability in all signals combines expected dispersion with utterly unpredictable uncertainty: $\text{var}(s) = \text{var}(v) + \text{var}(e)$. To match their decisions to market-based judgments of firm value, regulators must abandon their preference for retrospective, firm-specific information and embrace the inescapable uncertainty of evaluating forward-looking, comprehensive economic information.

In an metaphor befitting the tumultuous Anthropocene epoch, the law of regulated industries must now confront its own no-analog future.³⁶² All legal doctrines, from fair value in *Smyth* to the CAPM, remain extant. But environmental, economic, and technological conditions have reshuffled legal principles to such an extent that regulators must manage new circumstances with old tools, but no historical guidance.

Finer points of mathematical finance and constitutional doctrine ultimately yield to practical considerations. “It is not theory . . . which counts,” after all, “but the impact of the rate order.”³⁶³ Administrative consistency matters as much as intellectual cogency.³⁶⁴ “An important factor in the cost of capital . . . is *investor uncertainty* regarding future company or regulatory action that affects the components of total return on equity.”³⁶⁵ Because liberalized electricity

365. Gelhaus & Wilson, *supra* note 202, at 295 (emphasis added).

markets are prone to “some periods of high prices and greater differentiation between the prices paid by industrial customers . . . and [by] residential customers,” this industry faces an elevated risk of political intervention.³⁶⁶

Unless capital markets have a clear understanding of regulatory “methods to be employed in calculating total return, this uncertainty becomes an additional risk” factor that will “increase[e] the minimal return that [an investor] demands.”³⁶⁷ Although changes in the physical environment and the arc of technological progress may lie beyond the law, minimizing regulatory uncertainty benefits consumers and the allocation of resources generally.³⁶⁸

Legal consistency should bar either firms or their regulators from shifting arbitrarily between ratemaking methodologies.³⁶⁹ Such “an exciting new twist” in regulation “invites an enormous amount of gamesmanship.”³⁷⁰ Wholly apart from private firms’ motivation to exploit ratemaking rules, regulators face their own behavioral temptation. The asymmetry of regulatory risk may lure agencies into “arbitrarily switch[ing] back and forth between methodologies in a way which require[s] investors to bear the risk of bad investments at some times while denying them the benefit of good investments at others.”³⁷¹

Ratemaking formulas, whether couched in the logic of prudent investment, DCF, or asset pricing, fall short of offering comprehensive risk management. Even the most elaborate quantitative efforts to “give[] probabilities” for “various outcomes” make “no attempt to explain [the] underlying structure [of] price changes.”³⁷² Neither regulation nor finance can fully rebut Roll’s first critique, the objection that portfolio theory tautologically restates the capital asset pricing model, insofar as *any* mean-variance efficient portfolio is mathematically equivalent to the CAPM’s expected return.³⁷³

Tautologies such as $r = D_1/P_0 + g$, however, do serve useful purposes. What matters is that the tautology be “correct.”³⁷⁴ “All models are wrong; some models are useful.”³⁷⁵

DCF and the Gordon growth model epitomize the quest for a rate of return that attracts investment. The CAPM culminates nearly a century of regulatory wisdom garnered while “muddling through” the comparable earnings standard.³⁷⁶ Both of *Bluefield’s* ratemaking standards³⁷⁷ may be understood in terms of section II.B.1’s general model of financial uncertainty.

DCF, the Gordon growth model, and the CAPM are all special cases of the formula, $s = v + e$, which denotes an economic signal (s) as the sum of fundamental value (v) and noise (e). The basic DCF formula, , defines the rate of return as the ratio of dividends to share price, plus a less determinate growth factor. Rejecting the unrealistic assumption that investors “live for only one period” connects DCF and the Gordon growth model with more sophisticated models.³⁷⁸ *Investment-based asset pricing* defines the rate of return as a function of corporate earnings and stock returns.³⁷⁹ Conceptually, the rate of return should equal the ratio of a vector of future earnings from which a corporation pays dividends to the corresponding vector of capital investments:

$$r = \frac{\mathbf{e}}{\mathbf{k}} = \frac{e_1 e_2 \dots e_{n-1} e_n}{k_0 k_1 \dots k_{n-2} k_{n-1}}$$

This ratio amalgamates prudent investment with the basic ratio of earnings to price.

The regulatory CAPM, $r_u = r_f + \beta_u(r_u - r_f)$, likewise fits the basic $s = v + e$ formula. The second half of this formula, $\beta_u(r_u - r_f)$ may be

FIN. & QUANT. ANALYSIS* 44 (1996).

379. *See, e.g.,* John H. Cochrane, *Production-Based Asset Pricing and the Link Between Stock Returns and Economic Fluctuations*, 46 *J. FIN.* 209 (1991); Laura Xiaolei Liu et al., *Investment-Based Expected Stock Returns*, 117 *J. POL. ECON.* 1105 (2009). This approach should be contrasted with consumption-based asset pricing. *See, e.g.,* John Y. Campbell & John H. Cochrane, *By Force of Habit: A Consumption-Based Explanation of Aggregate Stock Market Behavior*, 107 *J. POL. ECON.* 205 (1999). Risk premiums unique to utility companies may be reflect macroeconomic pro-cyclicality between demand for utility services and returns on human capital.

conceptualized as the premium that induces investors to buy utility stock instead of a risk-free Treasury bond. We can express this idea, without loss of generality, through econophysics: If “[t]he optimal portfolio is . . . given by minimizing the risk σ^2 , given the return $\bar{r}$,” then “risk σ^2 is a quadratic function of the deviation of the portfolio return from that of the riskless asset, $(\bar{r} - r_0)^2$.”³⁸⁰

The inclusion of industry-specific beta within the regulatory CAPM provides a further illustration of generalized economic uncertainty. As a measure of variance within the economic signal that communicates a utility’s intrinsic value, beta decomposes into a basic quantum of risk, plus a premium indicating the reliability of the information used to compute beta: $\text{var}(s) = \text{var}(v) + \text{var}(e)$.

Most regulatory applications treat beta as if it were unconditionally reliable. Conceptualizing beta as a special case of information uncertainty, $E_t r_{e,t+1} = \gamma V_t + \theta M_t$ lets us define and quantify the “higher premium” that investors demand under uncertainty.³⁸¹ If we have confidence in our methods for quantifying risk, “so that $M_t = 0$, or if agents are not averse to uncertainty, so that $\theta = 0$,”³⁸² the more familiar linear regression expressing returns over a risk-free baseline, $E_t r_{e,t+1} = \gamma V_t$, within the CAPM is recovered as a special case of $E_t r_{e,t+1} = \gamma V_t + \theta M_t$, the formula combining aversion to risk with aversion to uncertainty.³⁸³ In mathematical as well as metaphorical terms, rate regulation must “wager [its] salvation upon some prophecy based upon imperfect knowledge.”³⁸⁴
